

THE INTERNET INDUSTRY THE STATE OF THE ART

MODERATOR

Pat Lane

Senior Seminar Programmer, Mecklermedia

SPEAKER

Joel Maloff

President, The Maloff Company

Pat Lane: Good morning, and welcome to Internet World. I'm Pat Lane, and I'm a senior program coordinator with Mecklermedia. I am here to introduce Joel Maloff, who will be talking to you about the Internet industry and the state of the art.

I would also like to mention that in the next session Joel Maloff will be replacing the speaker, so he will just continue on at 11:30.

Mr. Maloff is the founder of Maloff Company, which has dealt with the Internet. He has been a teacher, a consultant, worldwide consultant; as a matter of fact, he currently has his new book out, *Net.Profit*, sponsored by Mecklermedia and available through IDG Books.

Not to take away from any of his time, I am going to let him get started. Enjoy the session.

Joel Maloff: Good morning. Again, to echo what Pat said, we have had a cancellation in the second session this morning, which is "Leading The Internet: Who Are The Companies And Individuals That Drive The Emerging Industry?" What I will do is attempt to partly address some of the topics that were to be addressed by that speaker as we go through my comments this morning, and then just continue on so that we have more time. So, rather than take a break and stop as was planned at 11:15, I will just continue on so you'll have time for questions and for other information on that topic.

As Pat had mentioned, I do have a book that has just come out from *Internet World* and Mecklermedia, also published by IDG Books, that is available here at the show; and a lot of what I'll be talking about will be included in that.

I have been asked to talk this morning about the Internet and the state of the art as an industry. What I have chosen to do is to talk about this particular topic as to where are we today in the industry, how is it impacting businesses as end-users. I'm not going to be speaking to it from the standpoint of Internet access providers or Web out-sourcing or so forth, but looking at it from a user perspective — how does this impact you, what are some of the entrepreneurial opportunities, new jobs and so forth.

Now, to be topical and timely, since I'm talking about the state of the art, I thought it might be interesting to mention — I don't know if any of you saw *USA Today* this morning, but it seems that last week on Thursday a group of hackers known as "The Chaos Merchants" broke into Rodney Dangerfield's Web site and supplanted his opening screens with a picture of a naked woman. What it doesn't say is whether or not the naked woman looked like Rodney!

And what's interesting, moreover, is that the reason they found out that somebody had done this is that someone tried to download the picture, and had trouble and called in and complained about it. So as you can see, our industry is in a very interesting position.

Just to give you an overview of what I plan to cover this morning: I am going to talk a bit about organizational positioning using the Internet. What is it that companies are doing to position themselves to effectively take advantage of the Internet as a business tool, or suite of

business tools? We will also be talking about some of the cost-reduction opportunities, which I happen to believe are very important.

If you read the media today, if you look at the Internet, there are many people that believe that the Internet and WorldWide Web are synonymous. Clearly, they are not. One of the first areas that I as a consultant look at is how can organizations use this set of tools to be able to reduce expenses.

If you think about it, if you are able to reduce your corporate expenses by ten dollars, that ten dollars immediately goes to the bottom line. If you increase your sales by ten dollars and you have a margin of 10%, one dollar goes to the bottom line. From a corporate perspective I think it is important to look at all of the ways that these tools can and are being used by businesses.

We will look at marketing and sales, and clearly that's important. It's being done effectively in some cases today; we'll talk about what has worked and what hasn't.

We will also talk about internal communication. Again, this is another area that I think is often overlooked. Companies tend to think only externally — "How can I use the Internet to publicize myself?" — when in fact one of its greatest values and strengths may be in using it internally to better communicate with your own people, your own distributors, vendors, or otherwise.

And then lastly I will talk about what I refer to as "the entrepreneur's Valhalla." What are the new opportunities, the new businesses that are out there and emerging — or likely to emerge — over the next several years that will be able to incorporate and take advantage of the Internet?

Just a brief bit of background. As Pat mentioned, I have been involved with the Internet for quite a long time; I was Executive Director of the Big Ten University Research Network for three years, and I was Vice President of Sales and Marketing for a company called Advanced Network & Services, ANS, which was one of the largest Internet providers in the world for some time. I was Vice President of Sales and Marketing, and so I have been involved deeply in that area. Since January of 1994 I have been acting as an independent consultant and worked with organizations around the world to help them understand how they can reduce expense, increase revenue, or in some way tangibly contribute to the bottom-line mission of their organization.

I have worked with companies ranging from the Discovery Channel — we're very proud of the Web site that we have put up for them. I have worked with the National Football League, life insurance companies and companies throughout the world: Brazil, the Philippines, Australia, Germany. This is a worldwide phenomenon. I think it's very exciting. I think it's important to look at how it is being used and how it might be used.

I should also add that I will be taking questions, as appropriate, since we do have time. As we are going along, if there is something that you want to ask, please do. Raise your hand, shout out at me. I know this is a big audience. If you can wait until we get done with the prepared slides, that's fine as well. Anything you'd like to do, this is your session.

Now, one of the areas that I talk about in my book and in many of the other talks that I do is: Is the Internet a fad or a tidal wave? In my book, I say if you guess fad and you're wrong, you're going to drown. And to be honest, I think it's well beyond the fad stage. I want to briefly read to you some quotes from a *Wall Street Journal* article that appeared about three weeks ago. There is a company that is quite well-known, was very popular on Wall Street for a while, called General Magic that makes hand-held personal communicators. And in this particular article it says that like many other software and on-line services companies, General Magic has been blindsided by the explosive growth of the Internet and its graphical arm, the WorldWide Web.

I'm not sure I would characterize the Web as a graphical arm, but nevertheless the president of General Magic goes on to state that he had envisioned an electronic marketplace built piecemeal by AT&T and other telecommunications companies and accessed by hand-held communicators. But it's now becoming clear that the Web will probably be the main electronic marketplace and can be best accessed by personal computers.

The company goes on to say that "lots of companies were ambushed by the Net. I have a great affinity for the Internet, but only for the past year has it had any business visibility."

I think they're right at the bottom of that wave, waiting to get swamped. The fact of the matter is, the Internet is here to stay. What is critical for you as companies is to understand what it is, what it is not, and think of it again as a set of business tools that can be used to your advantage. Those companies that think it through carefully, that plan, evaluate, see where we are today and where we might be six months or twelve months from now, will be the ones that will succeed in the future that's coming. To ignore it and to say that it is a fad and just hype is to miss the opportunities that it represents today.

Now, from the standpoint of business use of the Internet, I think it is important for those of you that have seen the movie *Field of Dreams* to recognize that the Internet is not the "field of dreams." Unless you think it through very carefully, very thoroughly, understand what it is that it means to you, if you build it, they will not come. If they do come, they may not stay very long. And if they do come, they may not buy anything.

So it's important for you to understand what it is you want people to do when they see your cyberspace image that you create on the Net. We'll talk a bit about that this morning. It is not magic, and it does not work without a great deal of planning.

I have had people come to me and say, "We put up a WorldWide Web site and this Internet thing is terrible. Nobody came."

"Well, did you tell anybody you were there?"

"Well, no. It's the Internet. We didn't have to."

Wrong! It is the Internet, and it is just another set of business tools. How these tools are used, how well they are used or how poorly they are used, will impact you. We'll talk a bit about that further on this morning. And we are going to talk about what lessons have been learned thus far.

It is interesting; the Internet has been around for nearly thirty years, developed as part of the ARPANET project by the U.S. Defense Department. The WorldWide Web has been around less than four years, and Netscape, which is doing wonderful on the stock market, has been around less than two years. We are in a very, very new and evolving environment. What we take for granted today is new; we're just working out some of the kinks and some of the bugs.

What is important — and if I pass on any message to you today at all, it's this one — the Internet should not be technically driven. We should not be technology in search of application; rather, it ought to be driving the technology, [asking] "what do you want to do?" And then let's drive the vendors and Internet access providers and out-sourcing companies to deliver what you need, rather than what they think.

And that's true with security on the Net. It's true with front-ends and so forth. We'll be talking about that, but I believe the Internet should be a user-driven environment, and in fact it is becoming that. When I look at the Internet I try to look at what are businesses doing with Internet today. When I was at CICNet, I was trying to understand why our network traffic was growing at 20-30% per month, compounded. I asked our engineers, "what exactly is driving this traffic? What applications are occurring?" And their answers were: FTP, Telnet and e-mail.

I said, "You know, those aren't applications. Those are tools to do something." But what are we doing? I mean, are we sending recipes back and forth? Are we looking at naked pictures

of Rodney Dangerfield? What exactly are we doing? The answer was, "we have no idea, but isn't it great?!"

I don't think so. I think it's important for us to think of this again, not with all the mystique, not with all the buzzwords, but [as] tools. What do they do? And so I have been able to derive three distinct areas of business use over the past several years. The first is "rare remote" devices, and this includes everything that's too expensive to have everywhere you would like to have one: particle accelerators, space telescopes and supercomputers all fall in that category, but also medical imaging equipment, telemedicine, and remote imaging. In fact, during the Somalia relief effort, doctors in Washington, D.C. were actually looking at CAT scans of patients living in Somalia. That's remote telemedicine; it's actually being used all over the world. It does need high bandwidth, but it is using the Internet today. Even more mundane, from a business standpoint: distributed, computing remote client/server applications fall into that category. Your company is moving further and further away from big mainframes, its big iron. And so you've got client/servers distributed around the world.

How do you reach those servers that have the information that you require? One of the examples that I like to cite is a law firm that happens to be headquartered in Toronto, Canada, with a branch office in London, England. They will start working on a particularly difficult international law case first thing in the morning in London, work on it throughout the day, and at the end of the day they will place that information on a server, which is then accessed from their people in Toronto, where they continue to work on it for the remainder of the day. Their competitors are trying to figure out how these folks are working 18-hour days. Add an office in Sydney or in Hong Kong, and you can work 24-hour days. It is a new way of using your own corporate resources, distributing that information.

One other example of rare remote devices. Let's say that as a consultant you decide that you want my services; you want to sign my contract, but you're leaving the country tomorrow. I can't Federal Express it to you, it won't get there in time. You don't want me to fax it, that's not a good form for a legal document. You want the original, but I'm in Michigan, and you're somewhere else in the world.

If you give me permission, I have the ability to use the Internet to come across that network to your local area network and designate your laser printer as the output device, and print out my contract on your printer. You have it. You can do that today. That's rare remote devices, just one example of the kinds business uses.

The second area is information sources. We have gotten to the point with the Internet where we are absolutely overwhelmed with information. There's more than 14,000 network newsgroups, there are thousands and thousands of ListServers, Gopher servers, a hundred thousand Web servers out there. Not all of them are good, but there are that many.

How do you sort through all this? I think it is important. When you hear people throw out terms like the Internet is a marketplace of 40 million users worldwide, I don't agree with that. Sure, there may be 40 million people reachable in 172 countries on the Internet, but it is not a marketplace. That's like saying the world is a marketplace, or the U.S. or Brazil or Australia or Hong Kong is a marketplace. It's not true.

Instead, I believe that there are thousands of "micro-markets," or neighborhoods in cyberspace. And what is important is for us, as business people, is to identify the communities of interest, the neighborhoods that are of value to us. And we do that by using search tools to identify where these various resources are.

I'll talk a bit about some of those search tools in a few moments.

The last category is "intra/interorganizational communication." I used to refer to this as "interpersonal communication," and then it became clear that EDI, electronic data interchange, may not involve people at all; rather, it might be computers placing or receiving orders from

other computers, and so I refer to this as intra- or interorganizational. I think the intra- part is very much underplayed today. I mentioned that in my opening comments.

The Internet is a communications medium with a series of communications tools; how it can help you communicate internally is something that needs to be explored at great depth, along with how you communicate externally with customers, suppliers, sales personnel and service personnel, wherever they may be, anywhere in the world. It's important to understand where the value may be, and we'll talk about that as we go forward.

When you look to position yourself on the Internet, it is important to recognize that in cyberspace, image is everything. There is an absolutely wonderful cartoon that was around several years ago of two dogs, one sitting in front of a computer terminal, the other on the floor, and the caption is "On the Internet, no one knows you're a dog."

They also don't know if you are big or small, or where you're located. You could be located anywhere in the world. The beauty of it is that when you enter cyberspace you have left Boston, you have left Massachusetts, you have left the United States, and you are in an entirely new world. You need to understand the customs, the practices, how things work in this new world, because when you put your information up on cyberspace people anywhere in the world can see that information. They can see who you are.

When you send messages to people using even simple e-mail over the Internet, it is important to remember you should never, ever write something that you wouldn't want to live forever or be seen by your mother, because it will be seen all over.

I have learned the hard way that when you respond to a note from someone — I had somebody send me a note one time saying, "you know, I really think this person is a turkey." I sent the note back saying, "yeah, I agree, but they're really not that bad." What I didn't realize is that I had copied it to the person that was being criticized. I have a feeling some of you have experienced that as well. The point is, it's important to recognize what you're saying and where it can be seen.

I also have, as an aside, a bias that if you've ever seen notes posted from people who have an "xyz".com Internet address, they will have a disclaimer at the bottom saying my views do not necessarily represent those of my employer — and yet they're using that employer's e-mail service to make those comments. As a consultant, I tell my clients that I think they do represent you. If they're using an IBM or a General Motors or an AT&T e-mail address, and they're saying something and it's critical and not something you would want them to say, they are using company resources. That's just an aside; I think it is important that as you, as companies, start to use the Net more and more. You make sure your employees understand that these are corporate resources, and if they want to make comments that are inflammatory or otherwise, let them do it on their own, but not using company resources. It does reflect on you. Image is everything in cyberspace; you are what you appear to be.

I like to use the analogy that when you create an image in the Internet, it is very much as if it were a physical trade show exhibit. You can be using it to simply create an image so that people think well of you; you can be doing it to generate leads for future business, for future sales; or you can be doing it to actually close business right there on the spot — impulse buying.

It is critical that you think through in advance which of those you are trying to accomplish. I saw an interesting statistic not long ago that said that 20% of WorldWide Web sites were expected to be profitable by the end of this year. Well, what does that mean? How many of them want to be? How many of them are there just for image alone? And how many of them don't really know why they're there, other than we have to be on the Web?

So it is important to think through what are you trying to accomplish, what message are you sending. Are you in fact simply there for image? NorTel, formerly Northern Telecom, has a wonderful site that has a great deal of environmental information on it. It is very, very good. It

seems that the Northern Telecom people were required by the Canadian government to do a great deal of work on the environment. They have all this wonderful documentation and said, "What do we want to do with it?" Somebody said "Oh, let's put it on the Web." So they did, and they now receive all kinds of awards from schools and governments about all this great work that they've done.

Well, they didn't really do it for benevolent purposes, but they had it and they used it. Are they trying to sell you PBXs or central office switches using that? No. Are they creating an enhanced image? Absolutely! So that will be one that is not a profitable site; but is it benefiting them? Absolutely. It is important to think through what it is you want to accomplish.

As I look at most of the Web sites that are out there, it is apparent to me that insufficient planning and thought has gone into many of them. You will see in many cases what appears to be an electronic billboard; they have copied a brochure and put it up. It fails to consider the marketplace. It fails to consider the capabilities of the technology.

As you are creating a site, remember whatever you do is going to go into creating that image that will perpetuate your company, your organization.

I guess it was March of this year that CNP Publications, the people that publish *Interactive Age*, *Communications Week* and several others, went out and surveyed the WorldWide Web sites. There were thirty thousand Web sites they could find, of which they estimated ten thousand were business sites. They then went through those and picked their top one hundred Web sites in the world at that time — of course, it's many more now — based on how well those sites used the technology. That is up on the Net, and you can find it under tech.web. It's very interesting. There are hot-links to all of the sites, and those sites include some very big names, names like Netscape and IBM and AT&T, and some very small names, like The Maloff Company. It feels very strange for me, as a one-person company, to be on the same list with these huge companies with all these letters in their name.

The fact of the matter is, again, on the Internet no one knows you're a dog. They don't know that I'm a one-person company; I look the same as an AT&T. I think it's a riot, having worked for AT&T in the past.

But it is something that you can take advantage of as an organization. Remember, the image that you create is a lasting one. People don't generally come back to a site that they don't like, so you've got one chance to do it well. Think it through. Consider it as part of your overall marketing plan.

Now, I think it is important, too, that as businesses today are getting started they need to consider what expectations they have. What are they trying to accomplish? How many hits are you expecting on your site? Who are you expecting to come in? What are you expecting them to do when they get there? Who are you targeting? Where are they located? Are they domestic only? Are they international? In what countries? Why are they coming to you? Again, are they coming to you to gather information, image? Are they coming because you want to be able to use them as future leads? Are they coming to actually buy something from you? What are you trying to accomplish? Who is it that you are targeting?

What language are they speaking? You know, it is interesting. A year and a half ago I was asked what the de facto language is on the Internet, and it was English at that time. More and more sites are now moving towards other languages or choice of languages. In fact, there is a protocol being developed called "unit code" that would allow you to be able to access a site in whatever language you wish. I think it is important to recognize that even in this country — and I know there are many of you that are international — but even in the United States there are many people who are not native English speakers.

If you are using this as a positioning and sales tool, why not make it available to people in the language that is most comfortable to them, that will most accomplish your objectives,

whatever they are? Again, remember that you're in cyberspace. You're not in one location, you're reachable from anywhere. What is the objective with which you started out to begin with?

Lastly, test the waters. I think it is critical before an organization launches into an expensive program of any type that you have an idea of what you believe the benefits will be. I know, contrary to some views, I believe that the Internet is cost-justifiable. I do talk about that in my book. I have a template that I have devised to help people understand what are the business issues we are addressing; and by the way, a business issue to me is, "I want to reduce my inventory costs by 15%. I want to reduce my fax costs or long-distance costs by 20%." Those are business issues.

"We gotta be on the Web," ain't a business issue. You have to understand what you are trying to accomplish. Then you would have the ability to go in to your financial or executive people and say, "Here is what we believe we're going to impact. Here is what we believe the investment is likely to be, and here is the bottom-line benefit-to-cost ratio." It's a guess; it is not going to be perfect. But at least it demonstrates that you're thinking in terms of business issues, business relationships, rather than just thinking in terms of technology.

It is important to try it out. Test it out. See if it works. One of my clients is a very large insurance company. They wanted to create an Internet e-mail line very much like an 800 number where anyone interested in anything could call in. They wanted to have info at insurancecompany.com. I said, "You know, before you do that you might want to test the pipes and see what kind of response rate you're going to get, because you could have people calling on just about anything — policies that they want to claim, new policies that they want to buy, recruiting. Could be new sales agents. You could have any kind of calls. How are you going to handle the volume that will come in?"

And we didn't have any idea what that volume would be, so what we did as a test was to set up for their sales agent recruitment program at info-recruit@insurancecompany.com. All they did was add that e-mail address to the bottom of full page ads in *USA Today*, *Wall Street Journal*, and the *New York Times*. That was it. Didn't say anything more. 20% of all of the responses that they received in that initial campaign came in on the e-mail line. Now they have to figure out, what do I do with them? Who do I forward them to? They don't even have a coherent e-mail system throughout the whole corporation, so they were able to test the pipes, see where they were broken, and know where they fixed them without hurting themselves terribly.

It is important to test the waters, test the pipes before you roll out a plan completely. The beauty of the Internet is that it is interactive. You will find out very quickly what works and what doesn't work. Give yourself the space to be able to fix those pieces that may need correcting.

When we talk about cost reduction opportunities, one of my favorite is the fax. There is a Gallup poll that has been done for the past several years that indicates that the average large company spends 40% of its long-distance bill per year on fax. What exactly are we faxing? Where are they going? If you think about it, normally what we're doing is creating a document on a word processor, printing it out, handing it to someone who then puts it on a scanner — we call that a fax machine — and they then send it across a pair of wires, normally a dial-up telephone line, to a distant printer. We call that a fax machine as well, where we print it out again and either re-key the information or scan it one more time.

Why not just send it as an attached file? Why not just send the text, if you need to simply do that? You can. And I'm not asserting that you will reduce all faxes — you will not. But if you can cut your fax bill in half, that's 20% of your annual long-distance bill. You have the ability to start looking at tangible impacts.

Same thing with courier services. Why are we sending Federal Express packs or DHL or UPS all over the place? When I did my presentations around the world, I was doing a presentation in Brazil. I sent my PowerPoint slides as an attached file on an e-mail message. It got there within an hour; if I send it overnight it gets there in five days, and costs me fifty bucks. The fact of the matter is they have a usable file; they can translate it if they wish. They can print it out, whatever they need. It is much more effective.

Again, this will not eliminate all courier packs. However, I can tell you that when I was with ANS we had seven branch offices, and we sent out an overnight package to each of those branch offices every Tuesday and every Thursday whether we needed to or not. Why? It's because we had just always done it that way.

Think about how you're doing business. Think about ways that communications can help you be able to reduce those expenses. Long-distance voice costs. You know, it's interesting... When you call someone up to confirm a meeting, to confirm receipt of something, to ask a question, we are social animals. We can't simply call someone up and say, "Did you get my document? Thank you very much," click. We have to ask them how they're doing. We chat a little bit, and it builds up. On the Internet you don't need to do that; you can simply say, "Just checking to see if you got my note."

"Yes, I did."

"Thank you very much. See you for breakfast on Tuesday."

It works. You can actually reduce voice costs by the way that you communicate. I am a one-person company. I travel all over the world. If you really want to reach me, you send me mail at joelmaloff.com. If you call me at my office you'll speak to my voicemail, and what I'll tell you is to send me e-mail. That's the best way to get me.

Again, people are traveling a great deal. It is a way that works very effectively. Point-to-point leased lines are very expensive. Most of the large corporations have these. I'm not going to spend a lot of time on this, but companies are increasingly finding out that they can use Internet in a closed-user group or virtual private data network to communicate between their own branches, customers and suppliers as securely as if they were on their own private network.

It works. And it helps you not only to be able to extend the reach of your network more cost-effectively, because you can get the marginal sites, but also to potentially reduce costs from your network today. It doesn't work in all cases, but it is worth exploring.

The Trane Air-Conditioning Company is one I have worked with; they have replaced a 200-node SNA private network with an Internet solution, using closed-user group capability. You can quickly figure out that 200 nodes on a private line network is very expensive. They believe they have saved 25% on their annual communications costs by doing this. That's significant. I don't care how big you are, that's significant.

Personnel. You may be able to take advantage of having personnel in one office doing the tasks that had been distributed in the past, so again, you have the ability to explore how you can do more with less. This is the bad news. In fact, it was interesting; I was in the Philippines and a reporter there asked me a very unusual question. He said, "I want you to tell me, if you were a doctor and I was dying of cancer, I would want you to tell me the truth. What jobs is the Internet going to do away with?"

I said, "Well, I've never quite had it put to me that way. Perhaps there are some clerical jobs that will be impacted." However, as you will see towards the end of my presentation, I believe there are many more jobs that are being created than are being done away with, "cyber-entrepreneurs" and so forth. We'll talk about some of these when we get to the end. But, again, I think you have the ability to do more with less, and see how it can be of value to you.

Last is printed materials. I mentioned reducing inventory as a possible application that has been used by many clients that I have worked with. There are companies that are doing what is called “one-off printing;” instead of printing 15,000 copies of a brochure, knowing that some percentage of them are going to go obsolete before I can use them — and that some percentage of them are going to be damaged in shipping, or trashed so I’m never going to get to use all 15,000, and I’ve got to find a place to keep them — I have the ability to send the file of my brochures, my materials, to a printer and tell them, “I’m going to be at Internet World, deliver a thousand copies of that brochure to me at my hotel.” No inventory. I don’t have to worry about lugging them. They are timely; I can customize them for each show. It works. Printers are now increasingly doing this.

Now let’s say I want to do a show in Canada. Canada happens to quarantine printed materials coming in. My printer just simply transfers that file to a Canadian printer; the Canadian printer prints them out and delivers them to me in my Canadian hotel. Everything is great, I get them on time, and the Customs agents don’t even know what happened.

M: They do now!

Joel Maloff: It works very well. Yes?

M: Other comments about point-to-point leased lines?

Joel Maloff: Well, point-to-point leased lines are normally used in a private network environment. I believe that using the Internet can reduce the requirement for those, but not in all cases. For example, if they are being used heavily for voice communications between sites, the Internet is not a good replacement for that today. One could argue that it may be in the future, but I don’t think it is right now. I’m not sure what else you’re looking for on that point.

M: Fine.

Joel Maloff: Okay. Yes?

M: You wanted people to speak up...

Joel Maloff: Sure.

M: On your point there, exactly what we could call “Customs agent interference counter-measures?” I actually sent, like you said, courier service to Brazil; I couldn’t make it to the convention. I sent my materials to be presented, and they promised one-day service. The convention was in two days. It was held in Customs for about two weeks, totally missed the whole thing, and it could have been e-mailed or Interneted, and that would have solved it.

Joel Maloff: Yes. This gentleman’s comment is concurring with the comment about doing more internationally, that it does work; that you do have the ability to get information in a much more timely fashion that is usable.

You know, I don’t have it on these slides, but one of the other ones that I happen to like to use a lot as an example is sending out press releases. I send out all of my press releases electronically. I send them to newspapers, publishers and so forth around the world. The advantage is that when I do so, firstly they normally must read it. If I send them a paper press release, it sits in a stack of paper. Maybe they get to it, maybe they don’t. And also when they

do get it, it is electronically encoded, which means they can cut the information into their story and use it right away. They don't have to re-key anything.

The advantage of that is they spell my name right, and they get my e-mail address correct. It works. Yes?

W: I'm a little confused what you're saying about — and I'm very interested in it — getting something from your desk to a place that you're going to be giving a presentation X number of miles away. Are you saying that what you have set up at the hotel is a printer, and the hotel provides the opportunity for you to run off X number of things that you need to have run off?

Joel Maloff: No. The question is about my example and being able to do printing remotely. No, what I do is have a file of my brochure or a copy of my PowerPoint slides. I send that information either as an attached message on an e-mail message or using file transfer protocol. I actually transfer it to someone else's machine; they then have the ability at a printing press or a colleague's location to print that out.

So, no, I am not actually sending it to the hotel. Once they have printed out the materials — let's say we use the example of Canada — my printer has transferred the information to a Canadian printer, who prints out a thousand brochures and delivers me a box of them at my hotel so that I can then use them in this show. But they are not being printed on a printer at the hotel.

W: So you send them to the copy place?

Joel Maloff: Yes. I send them to a production facility in the destination or location I am going to be. The advantage is we miss Customs, I don't have to carry them, and they can be more timely because I can customize it to each show. I can say, "Welcome to Internet World Boston, come see me at Booth 334" on that brochure, otherwise you normally would print out ten thousand copies for economies of scale. I don't have to do that any longer because they're not doing typesetting as such; they are printing directly from the file that I have provided.

W: Just a follow-up question. Do you ever get nervous thinking that what if your file gets lost by the place up in wherever? I mean, there's some security in having the boxes done.

Joel Maloff: Sure. The question is, do I ever get nervous that they're going to lose my file? And the answer is, "No," because I don't send it the day before, really. I will send it several days before, and I will confirm via telephone or e-mail that it's been received. And they're local, so if I am sending the file to a Canadian printer in Toronto and I get to my hotel and they're not there, I go down the street and say "Where are my brochures? Print them off for me."

So no, I've never had a problem with sending information and having it get lost. Have I had a problem with files getting lost? Occasionally, but that is a rare occurrence. And, again, you can correct that very quickly.

All right, let me move on. Again, if you have more questions, I'm happy to take them.

Another area that we need to look at a little bit is how companies are using this for marketing and sales. And I am not going to read this slide to you, but I want to emphasize the point that marketing and sales are not the same thing; they are used in the same breath on occasion. But to me, marketing is the act of gathering information, finding out who your competitors are, who your customers are, who wants to buy your product, what they're interested in. Sales is the act of getting someone to say yes: "Yes, I will buy your product. Yes, I will subscribe to your service."

Now, in terms of marketing there are a variety of activities that occur. Gathering of information is the first; and the Internet is overwhelming with information. You have the ability to gather information on your competitors. Who are they? Where are they located? What are they doing?

As an example, I mentioned one of my insurance company clients. They wanted to know what their competitors were doing; I did a search and found several of them. One of them was one of their major competitors. We looked at their WorldWide Web site and it turned out that there were five bullets on the Web site. The first was nothing more than an electronic bulletin board; they had scanned in a brochure and that was it. It was boring. You look at it one time and it's done. The other four bullets were all very interesting, but next to each one was the word "future." We call that "vaporware."

Guess what my client now knows that their competitor is planning? And guess what we'll do better?

It is important to use the tools to identify what your competitors are doing, how they are positioning themselves. It is also important... I have one client that happens to be in a very controversial industry. They are a tobacco manufacturer. And doing a search on the Net, we found a large amount of information that was negative about their business. They may not like to hear about it, but they certainly need to know what people are saying.

Now, it is interesting; for that same client, doing the search for their competitors, we did find one of their competitors, and they happened to be listed in an on-line career center for job postings. We went and looked at the site for that company and it said "none available." That's not exactly the image that you really want to post. You want to have something that is of value and of interest, and you need to think about that up front.

Targeting customers. I mentioned the neighborhoods in cyberspace; how do you identify where your target customers are? Who should they be? I have often had clients ask me, "Well, how do we know who to target?" And I ask them, "Who do you target today? What is a description of the average buyer of your service?" Let's use those as keywords, do searches on the Net and find the neighborhoods, the newsgroups, the ListServes, the Web sites that they frequent, and let's observe those. Then let's announce that you are there.

You know, it is interesting... You're too large a group, so I'm not going to do it here, but quite often I will ask people how many of you have an e-mail address of any kind. I will then ask people, "How many of you also have an e-mail address on your business card?" Half the hands go down. Then I ask how many of you have any kind of electronic access, e-mail, Web site or otherwise, on your brochures, your advertising, your collateral material — and in a group of this size maybe I'll have five hands left.

Why keep it a secret? Tell people you're there! Let them know! You need to incorporate this within your existing communications vehicles. Put it on your letterhead. Put it on your invoices.

I was taking a train from New Jersey into New York City and we stopped at a train station, and there was an ad for men's cologne; and down at the bottom was www.cologne.com. I said, "you know, we've really made it when I can see a Web address in a New York City subway station." But it's important. I watch the World Series and see www.toyota.com on TV now.

It's come a long way. And what is important is for you to invite people to come see you. It isn't magic. It is not the field of dreams; you need to tell them you're there and invite them in. This is a common mistake that many businesses have made so far.

Environmental constraints. The United Nations has something called its International Trade Point Program, whereby they have created initially fifty servers in developing countries around the world. If you want to do business in rural Brazil or in Zimbabwe, you can log in to

these servers, find information on customs, trade regulations, maybe even get a listing of freight forwarding agents, and have their e-mail addresses to contact them. You can also provide your information about your products and services that are available in these countries. You can use the Internet to understand environmental constraints. So it is a valuable tool in marketing yourself.

Identifying resources. You have the ability to identify people, machinery, information that are out there and are of value to you. I mentioned earlier that I worked with Trane Air-Conditioning. They asked me in one of the sessions I was in to do a search on chlorofluorocarbons and "R-I Is." I had no idea what an R-I I was. I came from AT&T; I thought I plugged my phone into one. Actually, that's an RJ-I I jack.

R-I I is a refrigerant. I did a search on the Net — this is actually three and a half years ago now — and I found 58 hits. One of them happened to be from an environmental newsgroup and it was a professor from London, England talking about exactly the problem they were concerned about. They subsequently met with that professor, talked to him, and hired him as a consultant to assist them. That's based on a very simple search.

You have the ability to identify resources in many forms that are of value to you; and the way that you do this is through search tools.

Our search tools are getting better and better every day. Two years ago nobody ever heard of *Yahoo*; now it's the darling. And it's good. There's another search tool that I found recently that I like, called All-in-I. I've got the URL up here for you. This is a listing of probably several dozen different search tools categorized under WorldWide Web. There are probably 20 different tools, and when these come up there is a search box next to each one, so if you are doing a multiple search — recognizing that no one search tool knows everything — it only knows what it has been told exists, so you need to use multiple search tools depending on what it is you are looking for. You can just simply use a tool like All-in-I and go down the line and continue to look for them.

There are also resources to look for people. As you probably know, we don't have a great "white pages" approach in the Internet. As a way of testing these things, I normally plug in my own name, since I know I'm out on the Net and I know I'm visible. About three weeks ago, when I first found All-in-I, using the people section I plugged in my name and found two other Maloffs I've never heard of, one in Canada, one in California. And their e-mail addresses were located right there, clickable on that spot. So I sent them both a note saying, "Who the heck are you? Are we related?" So it is an interesting tool. I like All-in-I.

There is also another one called InfoMagnet. InfoMagnet is the only search tool I know of that actually searches and manages ListServes for you. It is very good; it does keyword searches on ListServes. I believe the URL is www.clark.net for InfoMagnet. If you do a search for InfoMagnet on *Yahoo* or some of the other tools, you'll find it.

Again, all of these are good search tools. There will be more that will help you sort through all of the information that is out there. This is the state of the art in search as we know it right now.

I am not going to belabor the point. Once you have gathered information, you need to be able to analyze it. How can you bring together people, resources, consultants wherever they might be, to help you analyze and evaluate the information that's out there? Now, I have clients, by the way, that I have never met, never seen and never spoken to. As long as their check clears and they like my work, who cares? It's a new way of doing business. I, as a consultant, am out traveling. They will send information to me; I will evaluate it and make recommendations to them.

This is just another brief point on accessing expertise. Again, you have the ability to contact these people because their e-mail addresses are readily available. So far we have been

talking mostly about free information. There also is an enormous amount of fee-based information available, whether it is the Dialogs or CompuServes out there, or America Online. In fact, I have the ability, even though America Online only has dial-up service at this moment in the U.S., I have the ability to access my America Online account from anywhere in the world simply by dialing into a local provider — I did this in the Philippines — and indicating on my America Online software that I want to use TCP/IP. So you can use it from anywhere in the world.

Yes, I pay for AOL, yes, I pay for Dialog or for CompuServe or for Mead Data. But it is available, and there will be more and more services at .com financial services that you will pay for because you want to pay for the quality and convenience. It is not always going to be free. There will be free resources out there; there will be fee-paid as well. It's important for you to determine what it is you need and what you are willing to pay.

Lastly, in terms of marketing, you have the ability to use the Internet to probe and test new markets as a real-time focus group or soundboard. The cult TV program *X Files*, the writers and producers follow some of the newsgroups, so that you as people participating in these newsgroups are helping them write their new scripts.

The movie *Star Trek: Generations*, a year before that movie was released somebody stole the script and posted it on the Net. Trekkers were very unhappy that Captain Kirk was shot in the back and bled to death; it was not a very noble ending. They changed the ending based on that occurrence.

Think about how valuable this would be to you in your business, to be able to get immediate feedback, whether it is e-mail, Internet relay chat, real-time, non-real-time reactions from people immediately so that you know how to adjust and impact your programs to make them work. What's important when companies look at selling on the Internet is that it is nothing more than an extension of your existing sales/marketing and business plans. It is not a stand-alone; it doesn't work by itself. You need to incorporate it. But recognize that when you have identified these neighborhoods in cyberspace, you invite people to come see you. You don't, as Kantor & Siegel purport to, send out messages to 14,000 newsgroups unless you want to get flamed. It's not a pleasant experience.

So what you do is identify the neighborhoods that are important to you and invite people to come see you. Once they do, it is a user self-initiated section and you can do anything you want. You can post your catalog, you can post your prices, you can ask for the sale. It's done all the time. You simply need to understand the tools and how they work effectively in cyberspace.

Is selling permissible? Absolutely. People have been selling for thirty years. It's just a matter of knowing how to sell, how to make it work, and how to incorporate it as part of your overall plan.

What is successfully being sold on the Internet? Anything that can easily be digitized: software, books, magazines, music. There are some wonderful music sites out there. Windham Hill Records has a great site. The Rolling Stones. You can listen to 15-second clips of the songs and decide if you want to go out and buy the CDs. Wonderful sites out there!

I have research reports that I have sold on-line that work very well. I know of software companies — in fact Microsoft has now just authorized the selling of their software by distributors over the Net. Now, the problem is if you have a 14.4 modem to download, I guess Microsoft Word would probably take about four and a half hours; so it is a little difficult.

But the point is, it's going to happen. In addition, anything that can [be sold] better be sold due to interactivity: printing services we've talked about, other products. I happen to be a wine lover; there are some absolutely wonderful wine sites selling wine on the Net. There's a great Napa Valley virtual vineyard tour with a map of the Napa Valley; you can just drive up

with your mouse clicking on different sites. It's absolutely wonderful! But the wines are just a little bit too dry over the Net for me... But it is a great way to begin to sell product.

Legal services. There are many legal firms that have sites. West Publishing's Westlaw service is available over the Internet. Charles Schwab, Fidelity Investments, all have sites on the Net. And I tell people, "Let's see if we can find one that doesn't fit. Is there something that can't in some way benefit from this?" And up until about nine months ago I was saying, "Well, the one thing I really don't like over the Internet is voice." Now we have *InternetPhone* and a variety of other ways to do it. That's occurring as well.

Again, it all comes back to individuality, what works for your business. When you are looking to sell, there are a variety of ways. There are the direct ways, the Web site that says "Come buy from me." Then there are indirect methods: electronic newsletters, participating in discussion groups so that you are visible. But remember that when you have a Web site, the only thing that you know primarily about people that have visited your site is what computer system they came from. So if they happen to be from CompuServe or America Online you know they came from there, but you know nothing more about them. You don't know who they are, how old they are, what demographic information might apply.

If you are building a Web site, it is important for you, if this is what you're doing with it, to be able to capture that information. Know where they went within your site, so you need to ask them. More and more sites are asking you to register, sign in so we know who you are. Recognize what they're doing is gathering both demographic information and possible lead information on you.

If you are putting up a site, recognize that you need to know this information and design that in. What are the demographics? Who is it that you are contacting? Where did they come from in terms of the type of service? What capabilities do they have? All of these types of information need to be consciously gathered on your part.

When we talk about internal communication, again I think this is an area that has been missed thus far by businesses. How can you take advantage of using these tools? Locally distributing corporate news so that your employees know what's going on. You have a new product that will be announced and the first time they see it, it's not in *USA Today*. They know about it in advance; they understand it. Your sales force knows what's going on. If you have people that are remote, if you have promotions, if you have changes, it helps to reduce the "Foreign Legion" effect: "I'm sitting out here in Seattle or Boston, corporate headquarters is elsewhere, I never know what's going on." It helps feel as if you're more part of the organization, and that can be very important in terms of morale.

Also in terms of internal organization, the Internet can be a wonderful tool for groupware software. There are a variety of efforts that have already been underway with Lotus Notes. AT&T has a Notes network. I'm not sure how that's going to change now that IBM is involved, but there is an AT&T Notes network. CompuServe has a Notes network, and Notes can be used across the Internet. Not very well publicized, but in fact several months ago Netscape acquired a groupware company called Calabria. You can read between the lines and see what they're planning on doing. Netscape looks like it might be competitive with a Lotus Notes environment. They're ambitious.

But, again, from a corporate standpoint it is important to understand how these tools work to facilitate communications across internal corporate lines.

Let's shift gears for a second and talk about what are some of the entrepreneurial opportunities that are occurring. Well, first I want to mention one that I think is closing. If you are interested in becoming an Internet access provider, especially in North America, the window is about closed. It's a little bit late, and unless you are very specialized either in

geographic or vertical industry niches, the big guys are here. So I wouldn't look to open a new Internet access provider.

For other countries where they are not well-represented yet, this is going to continue to grow. Non-North American access providers probably will have an opportunity over the next twelve to eighteen months, but beyond that I think we are going to see virtually every major country very well-positioned and penetrated with access.

Now, another area that is very interesting is Internet training services. It is becoming saturated. And I'm sure that all of you are bombarded with fliers for new training programs. The problem, though, is that they tend to be very broad-spectrum in terms of quality. There are a lot of people that learned about the Internet six months ago and are now experts, so it's important to identify what you are looking for in terms of training. Is it hands-on? Is it technical? Is it business application? And be clear on the capabilities of the training organization that you are looking to use. But training services will be around. This is a tool, and people are going to need to be taught how to use it.

I have been asked in the past by reporters that call saying, "when a company hooks up to the Internet, don't they have to worry about employees wasting time Net surfing all day long?" My answer is, well, that's sort of like saying let's rip out all the phones because I might call my wife to see what's for dinner. This is a tool, just like the copying machine is a tool and a company car is a tool.

We need to tell people how we expect them to use these tools and what it is they can do with them. So there will be a need for corporate training internally for quite some time, in my mind. There will be opportunities for entrepreneurs to do this, positively.

Internet hosting services. This is Web out-sourcing, other kinds of hosting where you out-source your services to a company that will do it for you. I am currently working on some research to evaluate this, and a lot of the consulting that I have done for my clients has been in exactly this area. We're a company; we don't want to build the infrastructure, hire the people even if we could find them. We want to pay someone else to do this. There are hundreds of these worldwide; how do you sort through them? How do you determine which ones have which capability? And if you are looking to get into this business, how do you position yourself as being more credible, more reliable than others? This is an area that is going to continue to grow and become customized with different types of performance as we move on.

Internet security services. I believe that this is the true growth area for both large organizations and small organizations, both security software and physical security devices, authentication devices like "smart" cards, biometric scanners like optical scans, retinal scans, fingerprint, thumbprint, voiceprint. These are all now coming down in price and are going to be much more widely available over the next several years. Again, working in conjunction with software. There are many, many opportunities we are going to see here.

Then virtual business services. These include language translation services. I want to do a proposal for you; you happen to be in the Philippines or Hong Kong. I do not speak Tagalog; I do not speak Chinese. So what I want to be able to do is send you on the Net my Microsoft Word proposal; I want you then to interpret it so that all of the context is correct. I'm sure that I'm saying what I want to say; you send it back to me and I can then submit it in the native language.

This is happening today. There are vendors starting to put up storefronts, making themselves available on the Internet today to do this. I think it is very valuable. We're going to see a move to more and more customization of languages; again, a great entrepreneurial opportunity.

Internet search bureaus. There are companies out there that instead of you having to spend all day searching the All-in-1 or Yahoo or WebCrawler or Lycos, they'll do it for you. It's

the 90's version of a clipping service, I guess. The fact of the matter is there is an opportunity there.

In addition, within your own corporation I believe we are going to see the role of corporate librarian, corporate information specialist become more and more important. I, as an employee in the sales and marketing, legal, or financial departments, don't want to be a specialist in *Netscape* or *Yahoo* or otherwise; I want someone that can tell me how to do it. That's another internal opportunity.

"Cybertectives." That's a cute term for people using the Internet for surveillance. Well, we've heard about all the hackers that are doing it for fun; what about businesses that are now going to do it for profit? You want me to spy on your competitors? I can do it over the network today without ever leaving. What about bill collectors, people that are trying to find deadbeats that have skipped out? All of these are opportunities to use the Net in new ways today. Now, if you're the deadbeat, I apologize! Sorry I put this bug in somebody's mind. But if you are a private investigation firm, what about using the techniques that are out there?

There is one I thought was really interesting. In doing some searches for businesses, I found the "Cleaning Clique." It's a cleaning service; they happen to be specialized, I believe, here in Massachusetts. But they're a cleaning service; they make themselves available over the Internet.

What is the possibility for promoting yourselves using the Internet, to be able to capture market or using the Internet as part of your deliverable? There are thousands of them.; it is just a matter that you need to think through as to how it impacts you.

So what's coming in the next year? Well, firstly, I believe that we're going to see more big-name Internet service providers, Internet access providers, in addition to the big names that are already there — AT&T, America Online, CompuServe, Prodigy, MCI, IBM, Sprint, Microsoft, Pacific Tel, Ameritech, NYNEX, are all now in the Internet access business. Most of them weren't a year ago. In addition to that, I believe that we will see the other regional Bell operating companies, independent telcos, long-distance companies; cable and wireless is about to be a force in the Internet.

Will they be as big as the others? Hard to say. But they will be there. LCI International, formerly called Lytel, again, another long-distance, fiber-optic-based. Bell Atlantic, U.S. West, Bell South — all Bell regional operating companies — will be in the Internet access business in some way, shape or form.

What about TCI, the big cable company? I think it is very possible that we're going to see some of the large cable companies become very active. There are tests that have been going on for three years now; there are cable modems that are becoming more and more effective, so these companies are likely to get into it. Apple may very well move out of eWorld into much broader Internet capability.

And then at least one non-North American U.S. provider will occur. I believe that we are going to see large providers from Europe or Asia start to come the other way, and the reason is as follows: If I am a multinational corporation, I have branches not only here in the United States but in Europe and in Asia. I want to have a provider that I can go to and say, "give me Internet access, dial-up, leased line, whatever it may be, wherever my branches are located." Today I can't do that; there is no one provider that has most major locations in the world covered. That's changing, with the announcements by UUNet and PSI and others. But I believe that we should not ignore the fact that there are other major players internationally, and this is a global market. There are no borders when it comes to the Internet. There are when it comes to PT&Ts and licensing, and so that has to be considered; but we will see transition as this becomes more and more of a global environment.

By the way, I should add that just because I'm saying these vendors are going to be in the game doesn't mean they're going to do it well. And doesn't mean they will succeed. There will be a tremendous amount of positioning, merging, alliances that will occur; and I think that's the next major step to look at. For example, will NETCOM, PSI, or UUNet be acquired by someone? It is not out of the question. Some of those companies that I mentioned on the previous slide may very well believe that the quickest way for them to gain market leverage and penetration is to buy one of these providers. And when you look at the prices that some of these organizations have gone for thus far, it might be a good buy for some of them. Again, I think it is an area that needs to be considered. I am not predicting this; I am saying it is a possibility.

Will IBM absorb Prodigy? As you may know, IBM and Sears jointly own Prodigy. I think it is very possible that over the next twelve months that Prodigy will become the IBM information service, just as Advantis is now the IBM global network formerly owned by Sears partly as well. Again, there is some logic there. Do I know anything inside? No. But I do watch the trends.

Will Colorado Supernet or Digital Express or DataBank or The WELL or any of these other so-called second-tier, primarily Internet access providers, go public? When you look at what the IPOs have done thus far, boy, that's very tempting. So we may very well see some other companies going public over the next year or so.

Will one or more of the regional Bell operating companies acquire an Internet service provider, an ISP? Now, I think that is very likely. Again, I look at companies that are late in getting started, whether it is a U.S. West or a Bell South or a Bell Atlantic; the quickest way for them to be in the game is to buy an existing Internet access provider. Whether they are compatible and whether it will work is an entirely different issue. But will it be something that will occur? I think so.

Additionally, American Internet service providers are going to be spreading internationally. We have already seen major announcements from UUNet, from PSI, from AT&T that they are expanding their international presence. CompuServe as well. In fact, as of several months ago CompuServe's revenues, their customer base, was only 65% North American; the rest was worldwide, with 25% from the Pacific Rim. I think it is very clear that all of these companies see this as a global marketplace and are going to be pushing in that way.

However, having worked internationally quite a bit, I believe that these companies will find a bit of difficulty in doing so. They may be perceived as invaders if they come in on their own, whereas if they come in partnering with organizations they are likely to be much more effective. It is going to be a very wild and interesting access game during the next twelve months or so.

Lastly, I think that physical authentication devices like smart cards or biometric scanners will become the hot item over the next twelve months, where they will be used as part of a complete network security plan rather than just saying, "oh, we need security, let's stick in a firewall." They don't work by themselves; they need to work as part of an overall plan in conjunction with a variety of other tools. So I think this is a new, hot area that you're going to see more and more about over the year.

As part of my concluding talk, for the first comments and for those of you who came in, the second session that was planned has been canceled, so we're going to continue talking about that topic as soon as I'm done with these slides.

Learning how to do business on the Internet is absolutely critical and will be unavoidable during the next year. Simply to say, "Well, let's just throw something up and see what happens," could be very damaging to your organization. So it is important to learn how to do it, test it out, try it out and see what works.

And then, lastly, it is important to take advantage of an industry that is evolving at warp speed. But it is going to be difficult; it's better to grab on and hang on than to be left in space dock.

So let me stop there. Are there any questions that I can answer on the discussion that we have had thus far? Yes? All the way over in the corner.

M: Referring back to when you were talking about some of the ways to use the Internet, i.e. anything that is easily digitized and transmitted... Regarding, say, music services or something like that, what are your thoughts or what do you see regarding copyright of that information? You mentioned the Rolling Stones and these 15-second clips and whatnot. How is that going to be done?

Joel Maloff: The question is, "What are the copyright issues when you have the ability to download something off of the Net?"

Again, I am not a legal expert on copyright, but my understanding is that they are copyrighted; that it is by governing law of wherever that area is. It is the same concern today as somebody taping a videotape and sending it on. I don't think the medium makes that much difference. It does make it easier to do, and there are some enforcement programs in terms of software that have been attempted. Yes, sir?

M: I am in touch with Ted Nelson — who is sometimes credited as the founding father of HTML, Hypertext Markup Language — and he answered that question differently. I bring to your attention that he proposes trans-copyright as a way to copyright things on the Internet. He says currently today when you put it on the Internet, it's in the public domain.

Joel Maloff: That's correct.

M: They can use it however they want to. That means you can copy pictures, you can copy text, you change the literature, you republish, it's completely public domain. So that issue should be further investigated with legal expert advice currently on the state of the art, what is trans-copyright law and what is copyright law.

Joel Maloff: Just to summarize, the gentleman says that there is a need to investigate trans-copyright law and new case law which hasn't been established yet. And I agree with that.

Other questions? Yes, sir?

M: Do we have to wait for these big companies to provide us worldwide ISP access? If not, how do we take our two or three hundred mobile sales force with local call access to the Internet, to the Web, et cetera, in the near term?

Joel Maloff: The question is, do you need to wait for one company to offer service globally or can you use multiple companies? The answer is, clearly you can use multiple companies. What is important, what I always recommend for my consulting clients, is to put together a list of your requirements. What do you need from providers? I call it a request for proposals. Submit it to the providers in the areas where you are looking to go and make sure that they address the specific concerns that you have.

You can do some follow-up, ask for reference checks and so forth. You may have them using different front-ends, different software. But once they're on the Net, it's all one happy

family. So, no, it is being done today but it does require more work on your part than if you had one provider that covered everything.

Other questions? Yes? In the front.

W: How do you see the smart cards aiding in security? Will everybody have their own little card and have an input device on their PC?

Joel Maloff: The question is, how does the smart card aid in security? Smart cards help create a very physical and finite definition that you are who you say you are.

I think it is going to occur in a couple of ways. The first way, for private companies, is that they can issue their employees a smart card, and so when they go to log onto a server they must authenticate themselves using that smart card. That's for a private environment.

For a commercial environment, I see the possibility of subscription services. Let's say I am going to have a newsletter that you pay for. As a startup fee, I charge you a \$100 startup fee, which includes a smart card — smart cards are about \$50 a unit right now — so that everybody that wants to get into my site then has to put in that code or run that card through a reader or whatever it might be. Those are the two methods that I see being used right now.

Other questions? In the middle.

W: Do you see maybe a smart cards will work, or do you see that everybody logging into everybody else's service, where there'll be a standard so I can log into a hundred different services and I don't have to put in my own unique ID and my own password? And also, do you think the security is there to be able to transfer personal information yet? Or is that coming? What do you think about that?

Joel Maloff: The question is, what about the possibility of having a smart card as an example that can be used in multiple sites rather than one site. And the danger there, of course, is the more you proliferate it the less secure it becomes. So yes, it is possible, but I'm not sure how I recommend that yet. It would depend on each individual situation.

The second question was, is the security there to transfer confidential information today? Using one of the smart cards that I am aware of, the ABN, Amro Bank in the Netherlands, permits you to transfer funds from one account to another, and that's pretty personal and that's being done right now. I happen to believe that, in terms of security, the Internet can be made acceptably secure if you understand what acceptable means to you. That means doing detailed research, developing a plan, understanding who you are protecting it from, why you are protecting it, how much it's worth to you. With all of that, you can put together an acceptable system.

Nothing is impregnable, so you need to understand what the acceptable level of risk is for you. But, yes, it can and is being done today. The ones you hear about people getting hacked into were for the most part ineffectively secured. Like Rodney Dangerfield's site. Yes?

M: What do you see as far as pricing goes for provider access? And also, as the big players like AT&T, MCI and all the other guys come in, do you see interaction from public utility commissions on establishing fixed pricing or something like that across the board? Essentially, what we see now as pricing has been factored into the future. Is it base cost, or is it going to go up?

Joel Maloff: The question is, how will pricing change, especially with large companies like AT&T and the RBOCs and IBM getting in.

I believe that pricing is going to come down a little bit from where it is today. We have seen pricing come down 30-40% over the past several years each year. But I believe it is getting pretty close to the stable level of where it should be.

You will continue to see multiple models. For example, you will see some pricing that is totally usage-sensitive on dial-up services - X number of dollars per hour, no flat fee. You will see some that are totally flat rate. And then you will see a variety of models where they're a combination: a flat fee with a usage fee for so many hours afterwards; or for leased lines services, what I refer to as a "stair-step." For the first layer, if you use it X number of hours or amount of time, it costs you this; but we're going to monitor it and if your usage starts to go up, then we bump you up to the next level. It is predictable and budgetable.

In terms of projecting costs out over the next several years, I think you can safely use the numbers that we're at today. It likely will be lower but probably not a lot lower, maybe in the 15-20% range.

M: And, again, do you see government intervention?

Joel Maloff: In terms of government intervention, most likely where that will occur is on the local level. And I hope it doesn't occur. The thing that concerns me, when you get into regulation, is that you start to minimize the ability of smaller entrepreneurial firms to compete because they don't have the ability to do the rate filings and tariff filings that the larger ones do. And it would be an artificial way of constraining a very robust environment that we have today.

I think before regulations like that occur, it needs to be examined very carefully, and I hope it is. Right now the market seems to be acting as a very good cover.

Other questions? Yes, sir?

M: Since there is no concept of quality of service guarantees, do you visualize an ultimate physical infrastructure which is tightly controlled by either telecommunication companies or big businesses, and the rest left to hackers and lot of personal communications?

Joel Maloff: The question is — let me see if I get this right — you're suggesting that the Internet may become the realm of only the large companies, and the rest left for hackers and smaller people? Was that your comment?

M: Yes. The way I see it, there are physical infrastructure alternates.

Joel Maloff: The Internet access companies today all buy capacity from the physical fiber-optic-based providers. But today the Internet as a marketplace is still specialized and relatively small, and I think it is going to be a long time before the large companies put out of business the Digex or NetXpress or other companies. Again, they are much more agile and this is a very rapidly moving environment, so, no, I don't see them being put out of business by the large ones.

Everybody thought that when Microsoft announced Microsoft Network that they would dominate the Internet and put everybody away. Not a chance! Don't think that's going to happen at all. Yes, sir?

M: Do you see information providers moving to off-line type communication as opposed to on-line because of on-line traffic on the Internet?

Joel Maloff: The question is, will on-line information users move to off-line services because of traffic? Actually there will be some of that. I believe we are going to see more and more CD-ROM technologies that have hooks into the Internet whereby it has the information. It might be large file size. I am looking at that information, but I want something that is current, like what has happened in the past month. I click on an icon; it links me into a Web site that is on the Net, seamlessly. So I think we are going to see on-line/off-line media connecting into each other. Yes, sir?

M: What kind of pricing formula do you see evolving this year in charges of flat subscription fees or hourly usage rates or fee for service, pay per hit?

Joel Maloff: The question is, what kind of pricing schemes will occur in terms of hourly, flat rate, or pay per hit?

I don't think we're going to see pay per hit in the next year. The problem is you have to determine what is a hit, and then the amounts are likely to be so small, you're not going to bill somebody a penny on a MasterCard, so I don't see that coming about. Again, I see continued evolution for access from where we are today that's either fifteen, twenty dollars a month for X number of hours and a per-hour rate on top of that for dial-up. For leased line access they will continue to come down, mostly being based on a flat rate; but as usage starts to go up, I think we are going to see some of that stair-step method.

And for the on-line services that charge a fee, each of them will come up with their own method. Some will be a subscription service: I charge you ten bucks a month and you can get in all-you-can-eat, but you have to have an authorization code, a smart card or otherwise to get in.

So that's likely to occur. Again, it is an entrepreneur's dream. Any and all methods are going to be tried, and the ones that succeed are the ones that are going to last.

Other questions? Yes? All the way in the back.

M: Do you see any long distance carriers changing their pricing mechanisms to the ISPs to packet-based pricing?

Joel Maloff: That's an interesting question. Are any of the long distance providers changing their pricing mechanisms to a more Internet-like packet-based environment?

I haven't seen any signs of that yet. But I know that both local exchange and long-distance providers are now very concerned about what impact the Internet will have, especially when you start seeing a lot of people talking about *InternetPhone*. I don't think it's going to yet put NYNEX out of business, but they're all concerned about it, and there may be new models for pricing their existing services. I just don't know anything specific about it right now.

Other questions?

Okay. The other topic we were going to talk about — and we're just about out of time anyway — was, "What are some of the companies and individuals that are driving Internet?"

There have been a variety of companies out there that I consider to be key drivers. Clearly, if you look at Netscape, Netscape has come from absolutely nowhere to be a key player in the Internet environment. But of all of the access players right now that I think are in the driver's seat, CompuServe to me is arguably the largest Internet access provider in the world. They have a huge customer base; they are transitioning them to Internet access and they are positioned well internationally. They will be very much a key player.

The Internet is also a community of personalities. There are many different people that are out there that are driving it, from the founders of UUNet or PSI, the key people within

Netscape and so forth; so we are going to see a very dynamic, evolving environment. It is important to watch out for these providers. It is also important to look, as I said earlier, at the new job opportunities that are out there. What new kinds of career opportunities are presenting themselves?

I wasn't really prepared to address that topic in any detail, so if any of you have any questions on that, I can take those as well. Are there any questions on that particular topic?

Well, you have been a very patient and quiet audience. We have gone over quite a bit on the time that we were allocated, and I am going to end it here. I will be up here for a few more minutes if you need to speak with me; otherwise thank you very much. You've been an attentive audience.

THE INTERNET INDUSTRY THE INTERNET IN 2010: AN INDUSTRY LEADER PANEL FORECAST

MODERATOR
Mark Lonergan
Partner, Heidrick & Struggles

SPEAKERS
Dr. Jay M. Tenenbaum, Ph.D.
CEO, EIT (Enterprise Integration Technologies)
David Garrison
CEO, NETCOM Online Services, Inc.
Stephen R. Levy
Chairman, Bolt, Beranek & Newman
John Patrick
Vice President, Internet Applications, IBM

Mark Lonergan: Good afternoon. Wow! What a crowd! Alan Meckler was describing the first of these conferences back in 1991, and according to him there were fewer people at that conference than are represented in this room today. Congratulations for finding your way here and, by extension, to this particular meeting.

Welcome to the “Leaders of the Internet” forum, and our study of the future of the Internet going to the year 2010. At this largely technical conference, our mission is to divert attention away from the technologies which will shape the Internet, and be much more focused on the real impact that the Internet will have on us as people at the cultural, social and political level.

Our goal at this roundtable is to stake out the big picture, to set our camera on a wide lens and to look at the basic fundamental issues that will shape our industry, and by extension, that will shape our world. By understanding these strategic issues, we will stir debate and help form some of the tactical decisions that confront the people in this room here in 1995.

In other forums you will learn what technology improvements will transform the Internet as a computing and communications resource. Here we hope to create context and foundation for that technology, and to give you some glimpse of the impact that we as a group will have on the future of this planet.

To perform this feat of prognostication, I have invited four individuals who have each had an enormous impact on the Internet already. I will introduce each more fully in a moment, but please let me introduce the four people who make up our panel.

First, on my left is Marty Tenenbaum, CEO and founder of Enterprise Integration Technologies in Menlo Park. On his left is Steve Levy, the Chairman of Bolt, Beranek & Newman in nearby Cambridge, Massachusetts. Next to him is John Patrick, Vice President of Internet Applications at IBM and based in Armonk, New York — or Galactic Central. And on his left is David Garrison, the President and CEO of NETCOM Online Services in San Jose.

My name is Mark Lonergan; I’m a partner at the executive search firm of Heidrick & Struggles, and am a founder of our unique Internet practice. I am a fifteen-year telecommunications industry veteran, having spent ten of those years at TimeNet, a well-known Internet predecessor — and although any of you from MCI might debate that, the rest of us consider it a predecessor!

To make this discussion a little more dynamic, I asked each of our presenters today to spend a few minutes discussing the future from his own perspective, and I think you will find that their observations will create energy for the discussion that follows. After their comments

we'll go interactive by talking among ourselves about the issues that affect us in the Internet community, and at the end of that discussion we will ask for input in questions from the floor and encourage you to participate as an audience.

Now let's set the mood and let's talk about a few non-Internet events that I predict might happen in the next ten to fifteen years. Suddenly we're at October 30th in the year 2010; we're transported, as Rod Serling might have said, through time and space. The world has become dramatically altered, and few can envision the enormity of the changes ahead. Here is just one portent of that world to come.

With improvements in superconducting materials and conduit, electrical generating facilities in North America have been dwindling in number in favor of much more massive, centralized facilities in Juarez, Mexico, and Akron, Ohio. The last remaining fossil fuel plant in the United States was decommissioned in March of last year, near Pasadena, Texas.

An earthquake measuring 8.4 struck off the central coast of California near Santa Barbara last September, causing the loss of 9,700 lives and over \$185 billion in damages. Highway 1 is not scheduled to reopen in sections for another ten months.

On the sports front, and perhaps on the whimsical front, Northwestern is looking to set a record and become the first "three-peat" Rose Bowl champion — I said three-peat Rose Bowl champion — despite the loss of twenty-two players and fifteen freshmen to the NFL in this year's draft. Parenthetically, none of the panelists have been able to guess yet where I went to school!

Greater China has finally surpassed the United States both in software revenues and in the number of Kentucky Fried Chicken outlet locations. Microsoft has more development engineers today in Canton Province than in the entire state of Washington. That's a scary thought.

Boutros-Boutros Ghali finally stepped down at the United Nations under a great deal of pressure, no longer able to explain the U.N.'s inconsistent military policy. His post went to the relatively obscure foreign minister from Georgia in a close vote of the General Assembly.

I'm an executive search guy, not a speechwriter.

Finally, on the medical front, four years ago scientists created the means to inexpensively join egg and sperm in the laboratory, determining the sex of the child and maybe other small genetic improvements. This advance alone leads to the births of over 18 million boy babies in India and only 3.1 girl babies in the year 2009. Bridal dowries disappear as part of a tradition in high-caste Indian families.

That's one man's view, my own, of some of the possibilities in the non-Internet, far-flung future. Our world will be shaped in the next fifteen years by both natural and man-made events; small direction shifts made today will yield astonishing improvements in the world of the year 2010. Nowhere is that more true than in the technology area and the industry that we now call the Internet. We are all affected by that, presenters and audience alike. We are at the jumping-off stage of a revolution, and some of the rebels who will lead that movement are sitting in front of you today.

Let's begin our review of the future. I would like to start this by introducing our first presenter today, John Patrick, whom you heard briefly introduced before. John, as I said already, is Vice President of Internet Applications for International Business Machines in Armonk. John has an EE degree, a BSEE from Lehigh University, and has both an M.B.A. and LL.D. degree as well. John was formerly, before his current post, Vice President of Marketing of what we now call the Personal Systems Division, and best known at IBM as the father of the ThinkPad from a marketing standpoint. John was also, earlier in his career at IBM, the Co-founder of IBM Credit, which has become one of the most successful efforts of its kind in technology. A 28-year IBM veteran, I am pleased to introduce John Patrick.

John Patrick: Thank you very much. (I am actually quite knowledgeable about the ThinkPad, but they insisted we use this unusual program called PowerPoint, and I must confess I'm not quite used to it. Okay, I guess it's going to work. See if I can bring up some video here...)

Well, good afternoon. It's really hard to speculate about what's going to happen in the year 2010. My friend Alan Meckler and I will each be starting our 44th year with IBM and Mecklermedia — or perhaps we'll be on the beach, enjoying the great job that our teenagers are doing as CEOs of high-tech companies who are totally Internet-oriented.

I would like to talk with you just for a few minutes about where I think we've been, where we are, and where we're headed as businesses, as a society or as individuals. Certainly we have seen a tremendous increase in interest and excitement about this thing called the Internet, from a curiosity to a media darling, from a grass-roots set of activities in my company — and perhaps yours and many others — to something that is discussed in the boardroom. Over at our company I have been talking about something called “get connected” for the past eighteen months. Perhaps some of you heard me talk about it at the keynote in San Jose in April; I talked about a set of ideas that can enable a company or a country or an organization to transform itself because of the Internet, to open itself up and become accessible and approachable, and to use these six simple ideas — which I will not go into this afternoon — to engage in dialogue with the constituencies of your organization in ways not possible before.

If you missed that discussion or if you are interested in this area, feel free to visit my personal Home Page on the Web at the URL you see there, and feel free to take a white paper that's there and read about it.

I think where we are right now is in an educational mode, and people are learning that the Net is really mainstream IT. It is not some phenomenon off in the corner that may or may not be able to perform, that may or may not be secure, that may or may not be good for our children. It's not a phenomenon. It's not C.B. radio, it's mainstream, and people are beginning to learn that. People are beginning to see TCP/IP not as something for UNIX hackers but as something that can extend existing networks. People are starting to wonder about massive disintermediation. Anybody who is a middleman or a middleperson, whose role is to aggregate information, is really looking over their shoulder right now, wondering what their role is going to be. And people are spending a lot of time talking about bandwidth; without it, it's not a lot of fun. And will there be enough bandwidth to do the things that people want to do?

In addition to this educational phase, a lot of issues make the news. Issues about security, encryption, privacy; issues about content rating and pornography. These are important issues, but issues that aren't yet really quite framed.

Now, where is this headed? Well, I'll give you just one person's view of this. I think by the year 2010, if not quite a bit before that, we will certainly see an Internet that is one Internet, a global Internet where all computers on the planet are connected to that one Internet. It will be a single network with portions of that network being protected; certainly with many of those systems being cordoned off behind firewalls, but nevertheless a single, global network.

We will see security that is not only understood but it is trusted and well-managed, something that people will take for granted. I think we will see open standards predominate; this is a very important thing to say, because I don't think we will see any vendor corner this opportunity that we all love so much called the Internet; I don't think there's room for proprietary thrusts to try to corner this and to make it into something that is developed behind closed doors. Electronic commerce, I believe, will be a major segment of commerce, not just an emerging segment but a major, significant one — hundreds of billions of dollars of commerce.

Software reuse is going to change the capabilities of IT to be responsive to our needs. Software will come across the network in reusable form, and will adapt as businesses and markets change. This “get connected” idea that I’ve talked about at Spring Internet World will be pervasive, and people will have complete access to companies and organizations, and those organizations and companies will have complete access to their constituencies, and companies who are responsive and agile will be prospering.

As individuals and as a society I believe that we will see an authentication of encryption, and will take it for granted and trust it. People will think of it just like we think of spell-checkers today.

The public will have access to the Web. I think a billion people, several billion perhaps, will have access to the Web, not with their own PCs, but through kiosks. People will take Web breaks off the plant floor, not smoke breaks. People will visit kiosks in their schools, their libraries, their churches... They’ll be in the jungle, and people will have access to the Web.

Bandwidth will not be a limitation. Today a 14.4 — think of that as a one-inch-in-diameter garden hose that delivers information to your desktop, and you know how fast that is at 14.4. By that time we’ll certainly have gigabyte capabilities, and one gigabyte is a 27-foot-in-diameter garden hose — and that’s the way we will think about bandwidth. It will be faster than our computers are today.

Physical communities will be based on lifestyles. You and I will live where we want to live, not where it’s close to commute to the people that we work for, because we will be able to work and collaborate on a completely geo-independent basis. We’ll live where we like to live, and the Internet will be a cultural and economic equalizer. Your next competitor may not only be in an industry that you never heard of, but may be from a country you never heard of.

So we have some exciting things here, and the greatest thing of all about this wonderful phenomenon that we all are so excited about is that you don’t have to wait for the year 2010. The future is now! All the things that can be done can be done now. It maybe a little harder, but you can do it. There’s an unlimited reach for business, an unlimited choice for individuals; it’s up to you and I to realize this wonderful future. It’s not up to IBM or Netscape or Microsoft or AT&T; it’s not up to any company. It’s up to the person on your left, the person on your right, you and I, to learn this technology, to share the excitement of it, to make a commitment to it, and exploit its tremendous potential.

So I think it’s a wonderful opportunity, and I think we should go for it and all “get connected.” Thank you.

Mark Lonergan: Thank you, John. I gotta tell you it was like pulling teeth to get him to install Microsoft, and particularly difficult when he discovered that once you had put Microsoft software in your hard disk, it never comes off.

Next I would like to introduce David Garrison. David is the President and Chief Executive Officer of NETCOM Online Services in San Jose. David — just a little bit of background on him — is a graduate of the Harvard Business School here in nearby Cambridge, and also has a B.S. in accounting from Syracuse University. Prior to his work at NETCOM, David was the President of Skytel, a worldwide paging company and division of MTEL in Jackson, Mississippi. And before that David was the Chief Executive Officer of a company called Dial Page in Greenville, South Carolina.

David is best known for both his career-oriented and non-career-oriented achievements, the latter of which include his work with Habitat for Humanity in Central America, and the sales and marketing job he did on his family in order to move from Jackson, Mississippi, to Los Gatos, California. If you’ve ever shopped for houses in Los Gatos, California, you know that was a heck of a job. David Garrison.

David Garrison: Thank you, Mark, and good afternoon, everyone. I'm a relative newcomer to the Internet, but I have had the opportunity and privilege to be in on the ground floor of a number of existing industries, and I think my comments and conclusions today will be biased by watching the cable industry being born, by watching the cellular industry being born, and now being in on what I consider the ground floor of perhaps the most significant development since the introductions of the telephone and the PC. So my bias in watching these other industries evolve will be reflected in my comments.

One of the things when you think about 2010 — as we're sitting here fifteen years from 2010 — one of the things we realize is that whatever we say today will be wrong. People say, "what's the future of your company?" I can lay out any future you want, but what I know for sure is it's probably going to be wrong, because we can't foresee the evolution of this business. So I say that because I want you to be aware that I realize I'm wrong in whatever I tell you about the future.

And I can tell you this because I've gone back to do my research, because I've gotten a time machine and went back fifteen years to understand some of the things people were saying. Perhaps Kenneth Olsen at DEC in 1977: "There is no reason for any individual to have a computer in his home." That could have been at this conference!

You think I'm going to make smarter comments than that?

But he's not the only one. I'm not picking on DEC, even though it's a local company. "Electronic mail is a totally unsaleable product." This is fifteen years ago, and remember electronic mail was not at a dissimilar stage from where the Internet is today and one could say, "Well, look how clunky it is, look how hard it is; you have to know commands..." A lot of things that could be said about the Internet today.

But it doesn't stop there. Alexander King at the Institute for Advanced Studies stated, "Ninety-five percent of us will be out of work by 1999 because of micros." And it's a plausible thing, if you take artificial intelligence and you project out the advances made.

I also remember I was told as a kid that we'd all have these backpacks like the Jetsons and we wouldn't have cars anymore, and we would all be kind of jetting around. But it's something about jet traffic control and airspace that stopped that one.

Other statements... Bill Gates, of course, in 1989 said "640K ought to be enough for anybody." I don't even know that your PowerPoint program could work on 640.

So that's why I come to you and I can say, "Look, I can talk about fifteen years from now. What I guarantee you is, I'll be wrong." I certainly don't have the intelligence of all these other folks who have made these wise prognostications in the past.

One thing I have concluded from watching these other fields being born is that it's not technology-driven. We see technology, and then we go on these wild projections of what this technology means. What I believe is the greatest variable in predicting the future is not technology, but in fact it's human behavior. It is answering very basic questions like, "How much does it cost, what does it do, why should I use it? Is this something new you're trying to convince me to do, or is it just an adaptation of something I do already?"

The rate of adaptation determines the viability of the application of technology, if you will. And that adaptation is how people in their everyday, commonsense lives answer those fundamental questions. It's not about, "Look at what this technology can do!" Frankly, nobody cares. In the conference it's very exciting and we'll all be abuzz for about three months about whatever is announced here, but the fundamental issue is, what does it mean to the end consumer, and why do they care?

I think that the test obviously has to be that the technology has to have obvious benefits, and serve a broad need, before people will adopt and embrace it. While there are no startling

revelations there, I think it is very important to remind ourselves of that, because sometimes we get all caught up in the technology and the breakthroughs that that exciting technology represents, but forget to ask some of the basic questions.

One of the things that's made the Internet so exciting, of course, as we look at it from a customer's viewpoint, is that we have taken away the scary UNIX commands from the average person. We have begun the process of demystifying the Net, and I think it becomes an obvious information and productivity tool for one major segment, and an entertainment source for another major segment of the population. And I think that's one of the reasons that our company has been blessed with this 460% growth.

I think, though, as we have seen in other places — for example the PC — that the software capability has truly lagged the hardware capability; we are still in a catch-up mode in the PC. And let me give you two examples of the PC, and how it relates to my comments that human behavior is what will drive it and that software lags.

If you look at the uses of most PCs on desktops today, I would venture that you would find two things. One, most are underutilized. Right? I can't tell you, as I go around the country, how many offices are playing poker. The incidence of electronic poker has skyrocketed, and I can draw a direct correlation with the introduction of the PC. We've got an enormous memory, enormous capability, without the software to use it.

The second thing is that the PC has basically taken the calculator, what the HP-12c can do, and put it on steroids. It's a lot more friendly display, right? But basically it's an HP-12c on steroids with a friendlier display and more memory. It is also a very juiced-up IBM Selectric typewriter. Haven't seen one of those in a while, but you do see a PC. Why is that? I think it's because those are the commonsense applications that the average person says "Yes, I can do this on this box."

But I don't think we have begun the PC revolution yet, because we haven't found beyond those two areas, we haven't found for the average person the real application, which I think will come along as we push the software edges and as we continue to push technology.

So with that as sort of background, let's see what it means for the future of the Internet. I think obviously it's evolving; we know that. We don't know today what it will be like tomorrow. It's interesting to see TCP/IP, as a protocol, is a fairly recent innovation. And as we have heard before from John, we agree the best bet will be open and flexible standards. That's why our company pioneered in direct Internet connectivity, and why we've said if you don't want to use our browser, what we are providing is a platform; you can plug in Netscape or other programs. That's because we believe that ultimately it will be about the customer's ability to customize the software around their own NAPs, and in fact, we will have many different types of Internet uses.

All that is background; let's move on to predictions. First of all, the Internet will be ubiquitous. It will be ubiquitous, but it won't be as we think about it today through the paradigm of a PC, because the PC provides way too much capability for what most people will use the Internet and its potential for.

Simple examples: browsing the Web from TV, [which is] very easily imaginable. There will be many inexpensive, single-use devices. We talk about applets today, but what is interesting, we talk about applets in a software vein; there will be applets in a hardware vein as well, single-use devices that are very cheap, eventually throw-away devices, which will eventually connect to the Internet. It wouldn't surprise me if these devices, for example, are wireless, voice-activated, single-application devices that are driven around obvious customer needs and behavior.

Now, until we can see how the whole "wireless" part and the "applet device" part evolves, it's hard for me to tell you what those might be, but it will replace something we do

now and make it easier and better. I doubt it's going to be some entirely new human behavior enabled by the Internet; I think instead it will be an adaptation to something we do now.

And the third point here is that I don't — frankly, I am struggling here. I hear all this about shopping on the Internet, and I have a lot of respect for what John said about billions and billions of dollars, and I hear that from AT&T, and I remember going into the labs there five years ago and looking at the electronic mall and seeing all the neat stuff I could do to order goods and services... And it just doesn't fly in my life.

I mean, I'm sure there will be a segment of people, maybe who are catalog shoppers, where it just takes off; and I don't think that means that there is not a future for electronic commerce on the Net. I think that we might get confused between the distinction of "enabling commerce" and "conducting commerce." What I mean by that is, I think we will go through a shift from "buyer beware" to "seller beware," because the beauty of the Net, as we all know in this room, is the ability for people with similar interests and dissimilar geographies, dissimilar politics, dissimilar nationalities, dissimilar races, it allows them to connect around areas of common interest in many different groups. It doesn't pigeonhole you into saying you're an American, or you're a Republican or a Democrat, or you're a PC user or you're a UNIX user. We'll see many different connections here.

What does that mean? It means the companies won't have the ability to be unresponsive to customers, and they are going to have to do a much better job of responding to customers' needs. It means customers will be able to compare notes about products and services before they buy. It means customers will have much better access to competitive information; customers will have much better access to evaluative information about that product, so customers will get much better educated, which I think, perhaps, the single largest impact of the Internet will be on our economy as we become smarter about spending our money. I think it will result in enormous fundamental changes in our economy; but not necessarily because you order flowers or something else through the Net.

So I'm yet from Missouri on the issue of, "will we be buying billions of dollars' worth of things through the Net?" But I do believe it will create billions of dollars of value in GNP, because people will be much better educated about how they spend their hard-earned dollars because of the Net.

So with that as a sort of backdrop here, one more quote. Thomas Watson, IBM, 1943: "I think there is a world market for maybe five computers."

Thank you.

Mark Lonergan: Thank you, David. The next speaker that I would like to introduce is Marty Tenenbaum. Marty is the Chairman and Co-founder of Enterprise Integration Technologies, a company he recently merged with Verifone, and is based in Menlo Park, California. Marty has a Ph.D. from Stanford in both electrical engineering and computer sciences, and has both an undergraduate and a master's degree in electrical engineering from nearby M.I.T. here in Cambridge. Before coming to EIT, Marty held the Schlumberger Chair in computer sciences at Stanford University. And prior to that, in his earlier work Marty is well-known for his work as a Co-founder of the Fairchild Laboratory for Artificial Intelligence Research, better known as FLAIR.

I would like to introduce Marty Tenenbaum.

Jay M. Tenenbaum: Thank you, Mark. I'm a technologist, not a prognosticator, and I prefer to live by the words of my former colleague, Allen Kay, who said, "Don't predict the future, invent it." Fortunately and historically, fifteen years is about the minimum amount of time that it takes for events that we see emerging today to get into the mainstream of society, and so with

anything shorter than that we are likely to overestimate the results; anything longer than that, underestimate. Fifteen years is probably just about right. So let's see where we're going.

I just want to put a couple of technological assumptions up as kind of guideposts to where I want to extrapolate from. These look very consistent with what all of the speakers have said so far; namely — but I will say it in a slightly more provocative way — there is not going to be an Internet in the year 2010. There will merely be a Net, and this Net will be provided most likely from the telephone company or something like that. And all kinds of things will plug into it, for all kinds of different purposes. We've got the obvious appliances up there, from PCs — personal communicators — to TVs, but you can take the word “appliance” literally. Your coffee maker may well plug into the Net — and that's the real HotJava. Jim Gossling, who is the inventor of HotJava and the Java language, likes to talk about having enough IP addresses to be able to connect every light bulb into the Net, at least metaphorically, as kind of the order of magnitude that one is going to need for controlling things.

So there's going to be a lot of things plugged into this information infrastructure. Running on those machines are not going to be net browsers as you know them today; they are going to be applications of all kinds. You're going to be sitting there using your word processor and calling up documents that you want to incorporate; you'll be using a CAD system and calling up designs or analysis services and the like.

In terms of David's comment about wanting to have shopping be a richer experience than you get on the Web, these immersive environments, 3-D collaborative environments, will certainly put some amount of fun back into shopping, though I certainly agree that people are going to want to get together socially, at least hopefully.

The real legacy, the lasting legacy of the Internet — what we have accomplished, I think, over just the last couple of years and what I think is going to persist well into the 21st century — are these two items down at the bottom, “flat pricing” and “openness.” By flat pricing what I mean is that you will pay for bandwidth, the width of the pipe that you're using, and that might in fact be variable, but you will be not paying per call. The number of calls, the length of the call, the distance of the call, that's all flat. And the second is openness, the fact that anyone can plug into this thing.

Those two factors together are going to be some of the most profound economic and social drivers that are going to affect society.

The principal effects are going to be freedom and empowerment, unprecedented choices about where everyone can live, the kind of work you do, and as a consumer, the type of choices that you are able to make. You will be able to get hundreds of quotes, if you want, on an insurance policy, or get ten Lexus dealers to bid on providing you a Lexus. You will have the information that you need to make informed decisions, whether it be who you're voting for or what you're buying. And I think that is very consistent with what the last speaker said as well.

There are, of course, losers as well as winners, and I think the real estate industry is quite likely to be a loser. The prices of real estate in the financial district of Manhattan are already falling precipitously, even compared to the prices in the rest of Manhattan, and that's a trend that is likely to continue. I think we are going to continue to see some job losses in certain, perhaps financial, services industries and other kinds of traditional middlemen.

But the thing that's most unsettling to the stakeholders, the big businesses and governments, is what's going to happen because of the Internet's ability to level the playing field, and this notion of bypassing gatekeepers and crossing international borders basically at will. I think it is quite plausible to imagine the death of distribution monopolies, which have basically governed commerce ever since the days of the cities on the rivers dominating commerce, and right up to certain software companies dominating shelf space in software stores. That is going

to change. And in the very same fashion it is not at all clear that nation states will be able to continue to control the issuance of currency, be able to collect taxes and tariffs and so forth. So some really profound changes there.

I would now like to spend the next few minutes going through some specific sectors of society and commenting on what I think are really clearly trends from what exists today.

Starting from an area which I spent most of my time on, which is doing business on the Web, I have basically simplified my view of what's happening here to a single Chinese word; and that word is "crisis." And the reason why that's appropriate is because crisis, as shown in the calligraphy in Chinese, is the juxtaposition of two characters, one standing for danger, the other for opportunity. The danger, of course, is that anyone and everything is in danger of being bypassed, disintermediated. The suppliers, for example, once everyone is connected to the Web, can perfectly well deal with consumers directly; they don't have to go through merchants. Banks can deal directly with other banks over the Web; they don't have to go through "VisaNet." Merchants can disintermediate each other; so, for example, a merchant can get blindsided by a competitor they don't know about from around the world, or from a "meta-merchant," if you like, who puts himself up on top of the other merchants and simply says, "Come to me and I will go query the other merchants and give you the best price on a CD," or something that you want to buy.

So it's real easy for someone else to insert themselves between you and your customers; and the value proposition for these kinds of merchants is very, very compelling. The consumer places an order, and this virtual merchant doesn't do anything other than accept the order and pass it on to the distributor, who deals with fulfillment. So he has no inventory, he has no employees, he can do basically anything that he wants.

So these are the forces that are happening in commerce, and my contention is that very similar things are going to be happening in every sector of society. Take, for example, manufacturing. Today an engineer who wants to design something is typically sitting at his desk, working with colleagues and thinking about the capabilities that his own vertically-integrated organization can provide. That's not going to be the case once everything is connected to the Net; he will be dealing with all kinds of other services that are willing to license him designs that he can build on, [dealing with] analysis services where he can send the design, get it run on a supercomputer, get back a movie annotated by an expert, and then send the part out for fabrication. All those types of things, leading to a hundred billion dollar design-and-manufacturing services industry on the Internet.

The implications of that are many things, like mass customization and so forth. But I would like to dwell on one in particular, which is basically the disassembly of large, vertically-integrated organizations. Companies will tend to focus on their core competencies, because once you can go outside for services just as easily as inside, if you can get better price, quality and delivery on, say, a printed circuit board that you want built, that's where you'll go. And the company that used to have a printed circuit board shop will get out of that business and stick to the things it does best.

This provides tremendous opportunities for the small businesses that are going to be providing these services, and for them to act, in a virtual enterprise sense, as large companies themselves. A small shop can bid on a big job on behalf of lots of other shops that it is going to sub the jobs out to; or even the small shop that just has design expertise can put together a project for doing a new automobile and bring together all of the capabilities that it needs over the Net to go do that.

And switching to a whole other sector, I think about higher education, which is driven by some clear economic forces. It is going to have to change, and the change is motivated by things like declining budgets in the face of some declining enrollments. At the same time,

knowledge is exploding faster than the number of journals and the library space available to house them; and yet there are opportunities as well. While enrollment may be declining during the three or four years that people traditionally spend at a college, the opportunities for lifelong learning, “just-in-time” on the desktop, are increasing. And information technology is, of course, the enabler that is going to make that possible.

Let’s look at the virtual university. Take all of those constituencies that are represented by the university today, students and staff and professors and researchers and librarians and the like, and plug them together on the Net and imagine, in principle, a virtual university that might have a million or five million participants around the world.

The graphic, by the way, is from a really early example; this is Jones [Sinders] Cable Mind Extension University, and you can visit them on the Web.

So if you think about the kinds of services that might be available, a student starts by looking in a catalog for courses; they can get to see video snippets of what they’re doing, then register for courses or review their transcripts. Courses can be put together, national courses by the best people in the field, building on each other’s work, and then make those available on a fee-for-use basis, perhaps only in modules of ten minutes at a time, if you need that for just-in-time education.

Academic publishing is going to be radically changed with the ability to have on-line papers where people — these are multimedia papers — you make your data available, you’ve got runnable models. All of this sort of stuff doesn’t need physical library space, either, and as far as the administration of a university, this is a business, and just like any other business it can benefit from the kinds of choices and outsourcing that we talked about a second ago with respect to commerce.

Health care is a much different industry, on the surface, from universities, but facing very much the same economic forces. There are the constituencies in health care — everything from consumers to insurers, with doctors and nurses and whatnot in between — let’s plug all those people into the Net and basically have an on-line, virtual health services organization. And the kind of things I’m looking for there are, of course, patient data records on-line. But it is not like I want to re-engineer a national patient data record system; there’s plenty of patient information that exists today all over the place, but it’s just redundant or disconnected. And we would like to build federated systems, so that when someone comes into the cloud — like someone that you saw in the commerce slide — with the right credentials and authorization, they can get directed to the place that has the information and get it, thereby saving patients considerable expense and risk and discomfort from redundant procedures.

But more importantly is to take the patient information, add medical information and on-line collaboration, bring that all together, and you have the ingredients for profoundly better medical decision-making, all coming out of this same fundamental thing.

So I have two left; I’ll go through them quickly.

Publishing. Today’s print media involves very expensive procedures for being able to get a book together and publish it, and the control of the distribution channel is necessarily centralized because of the investment required. That really limits the opportunities for individuals to add value to this process, especially small, incremental amounts of value.

Let’s move ahead fifteen years and look at the emerging, what I call the “on-line marketplace” for publication products, in which basically everyone who is a reader is also a content provider, even people who never thought of themselves as merchants. Someone who just likes to write recipes or what-have-you can sell this stuff, and they can make use of any or none of the publishing services that they need. They can become their own publishers or they can make use of selected services that a publisher provides, whether it be editorial, illustrators, translators, or distribution or what-have-you.

The real opportunity is for the information intermediaries. With so much information available there will be a compelling need for people to provide all kinds of directory, referral, annotation and indexing-type services, and they will be able to charge for those things maybe a penny or a nickel or what-have-you. And with the number of people in the billions on the Net — right? — if you get one in ten thousand people to use your service, you will be very well off indeed.

Very much the same thing is going to happen in the broadcasting industry, where things are going to go towards not five hundred channels but five billion channels, where five billion might be an estimate of population in the world in 2010 — or maybe it will be ten billion if we're not lucky — and [it will be] highly interactive where, again, everyone will be a provider. You will be able to tune in to the "Marty Tenenbaum channel" for my fifteen minutes of fame that's once in your lifetime, if you might have gotten inspired on a particular topic.

Clearly these types of things that I've been talking about for the last ten minutes are going to have a profound impact on society. How big? Maybe this big... This is a quote from *The Economist*, a conservative and very perceptive publication not normally known for exaggeration. It's a comment on the Internet in a special issue; it says the impact is likely to be "ahead of the telephone and television, but behind the printing press and the motorcar."

Certainly makes for provocative reading. It is very hard, of course, to tell exactly how profound anything is going to be.

I think the important point to take away from this session is that this is a phenomenon that you cannot ignore. It is going to change the world, and the profound changes are going to come from the fact that everything that I have been talking about is not going to be something in isolation for the university, or health care, or manufacturing or what-have-you. All of these things are going on simultaneously, all connected to the same Net. And it is the unanticipated, indeed unpredictable, synergies between all of these phenomena going on simultaneously that are going to lead, as they always do, to the really profound changes in society.

So the fact that you're here is a very good sign. You will not be bypassed. Thank you very much.

Mark Lonergan: Thank you, Marty. The last speaker this afternoon before we go interactive will be Steve Levy. Steve, as many of you know, is the Chairman of Bolt, Beranek & Newman in Cambridge. Steve is a graduate of the University of Massachusetts with a B.A. in finance; he joined BB&N back in 1966, becoming its President and CEO ten years later. Steve grew BB&N from a small research and development company with national ambitions to an internationally recognized technology company that has become a true leader in the Internet, starting in the early days of ARPA.

Steve, aside from his work there at BB&N, is something of a fixture here in the Boston area. He is a former Chairman of the Massachusetts High Technology Council, was the Founder of the Massachusetts Telecommunications Council, Chair of the AEA —the American Electronics Association — and is on the Board of Overseers of the Boston Symphony.

I am also told he was on the Board of Directors at one point for the Federal Reserve Bank, District I here in Boston, so if you have trouble with your mortgage rates, he's a good guy to talk to.

Just briefly, at the end of Steve's presentation, he also has an extra presentation that he has gleaned from other esteemed leaders of the Internet, and I'm sure you will all enjoy that. Steve Levy.

Stephen Levy: Thank you and good afternoon. It is a great pleasure to be on this panel with Dave, John and Marty, and I want to especially thank Mark Lonergan for organizing this session and inviting me to participate in it.

Most of us who had the good fortune to be present at the birth of the ARPANET and its successor, the Internet, never dreamed that their development would take us so far so fast. Now, as we think about what might lie ahead, it is only natural to look back to see just how far we've come.

While fifteen years may seem a long time into the future, it really isn't. To put things in perspective, it was just fifteen years ago, in 1980, that IBM announced its plans for the first PC. Apple and other companies were working on microprocessor-based computers before 1980, but it was the launch of the IBM PC in 1981 which legitimized the industry for the rest of the world and served as the benchmark for the computer revolution that we are in the throes of today.

Just think of how much the PC has changed during the past fifteen years and how much it has changed the world. I believe that the Internet is likely to have just as profound an impact on the world over the next fifteen years as the PC has had over the last fifteen.

Remember those first PCs? They had a 4.77 megahertz Intel 8088 CPU, 64 kilobytes of RAM, 40 kilobytes of ROM, a 5-1/4-inch floppy drive and they came with MS-DOS 1.0. The list price was \$3,000.

I picked up the newspaper over the weekend just to see the going price for PCs today. In one ad, a top-of-the-line PC clone with a Pentium processor, 16 megabytes of RAM, a 1.6 gigabyte hard drive, a 15-inch color monitor, a PCI graphics card, a 28.8 BBS fax modem, a quad speed CD-ROM, and about a thousand dollars' worth of bundled software had a list price of \$3,000. The price tag is the same, but what's under the hood is light-years ahead.

The PC obviously also had a lot to do with bringing about the dramatic growth in networked communications, including the Internet as we know it today. Largely because of the PC, we have seen incredible growth over the past fifteen years in the software, semiconductor, electronics and communications industries. The application of products and services provided by these industries has in turn led to increased productivity and growth in many other sectors of today's global economy.

So what do I think the future of the Internet will look like in fifteen years? First and foremost, I believe that continued development of ever more powerful hardware and software, allowing easier and faster access to vast resources of information and entertainment, will within fifteen years make the Internet nearly as ubiquitous and pervasive as the telephone is today.

In fact, I wouldn't be surprised if some of the things discussed on the panel today come to fruition long before the 2010 time frame.

In the year 2010, the Internet, or whatever it's called then, will be accessible from almost any location in the world with extremely easy-to-use input and output devices, including, very importantly, speech recognition and speech synthesis. Your computer will likely be a fully integrated distributed system in your office, car and home. It would perhaps best be characterized by what is not around then; there'll be no need for a phone, no keyboard, no visible computer or teleconferencing device in your office. At home there will be no TV, no VCR, no stereo, and perhaps no newspaper; instead, your fully-integrated, digital distributed system is part of a web of such devices that satisfy all of your "infotainment" needs. It gives you what you want, where you want it, when you want it.

Physically it may take the form of a large flat panel display with a color camera, 2-D microphone array, huge-capacity hard drives and giant RAM configurations. These infotainment units will appear as slim, non-obtrusive wall-mounted or desk-size picture frames, and sell at prices comparable to today's PCs and workstations. With them, in the year 2010, users will be

able to request anything the Internet can offer in its millions of databases and servers: virtual reality, full-motion video, and digital sound.

While we're speaking about price, the cost of accessing information from this vast digital repository will likely also change. Already we can see the start of a move away from free service to fee-based facilities. Unlike today, the Internet connection may be virtually free, but increasingly companies will charge users to access certain of their Internet-based resources. The free Internet services will be very robust; they will include facilities for electronic commerce, multimedia publishing and an underlying, secure network infrastructure.

The Internet will also grow in new ways that we cannot yet comprehend. Each new technological advancement will point the way to even greater things. The Internet will speed up the rate of new software development, because engineers will be able to find and retrieve reusable code from multiple libraries on any subject. This is already starting to happen; and the resulting products will shape how we access and process information in the future.

Interacting with the Internet will get much, much simpler. Users will be able to select a front-end they feel most comfortable with, be it a Web-like interface, speech recognition or some kind of virtual reality. Internet search and retrieval tools like *Yahoo*, *Lycos* and *WebCrawler* are already having a profound impact, and we are just at the first stages of search and retrieval technology. Multimedia search capabilities will be routine in the year 2010. Speech recognition will free users from manual typing, and intelligent search agents will travel the lengths of the Internet to uncover information that users are interested in and customize it in a format that is pleasing to the recipient.

The Internet of 2010 is likely to be used more for entertainment and leisure than for work. We are already witnessing the convergence of information and entertainment; in 2010 it will be seamless. The convergence of HDTV, computing and communication will make your home or office a virtual theater.

On each wall may be a three-by-four-foot infotainment unit, and a 2-D microphone array will automatically focus on your voice and minimize the effects of reverberation, and thus you will be free to interact with the system from anywhere in the room. It will recognize your voice and accept commands spoken in natural English, and speaker authentication technology will make sure that only you and other authorized users have access to the system.

The unit will have an extremely powerful computer "mother chip" built into it. It will also have enormous memory and be connected from behind to AC power and a fiber-optic cable, which will be connected to a terabyte router in the basement of your building, where it is in turn connected to the Internet.

The unit will contain very powerful "knowbots," or knowledge robots, and executive assistant software that enables the unit to learn your likes and dislikes, how you do your daily work and what your preferences are. It will select and customize your information and make recommendations accordingly.

Libraries of films will be at your fingertips. If you are interested in a movie, you can take advantage of the system's video-on-demand capabilities. You can scan through a virtual *Lazy Susan* containing thousands of movies, and can preview any of them; When you find the movie you want, you can purchase a virtual ticket. Just as movies will be available when you want them, so too will concerts, lectures and sporting events.

Interested in World Cup soccer? You will be able to access not only the latest game results and high scores, but also have daily packages of highlights transmitted to your home.

In short, your neighborhood will be global in scope. The opportunity for using the Internet for leisurely pursuits will be astronomical in 2010. Every special interest will have a forum to share information and opinions. Take mountain biking, for example; in 2010 the Internet's mountain bike forum may help you plan your next trip. You can preview different

riding spots, strap on a virtual reality helmet and take a ride as well as talk with other people who have ridden these courses. You can also search the network or, rather, have the network searched, to find hotels in, say, the Lake Tahoe area, that offer package deals for mountain bikers.

While we're talking about trips, you can set one up easily through a live connection between you and your partner using video-conference technology and virtual travel agents. You both review your itinerary on-screen, you from your living room and your partner from his or her office. Using speech commands, you can specify the cities you want to travel through and can call up video for different points of interest and participate in travel discussion groups.

Once your plans are firm, the same system will let you purchase tickets for flights, as well as for museums or shows, and make reservations at restaurants and other stops along your trip. And if you have questions, an on-line travel agent will come on the screen to explain, for example, which countries require visas and which don't.

As you would expect, kids will continue to be very heavy users of the Internet fifteen years from now. They will be able to search the networks for thousands of multimedia and virtual reality learning programs and entertainment games. Perhaps your grandson will learn to read with the assistance of a program on the Internet which encourages him to read aloud while it corrects his mistakes, fills in words he doesn't know, and gives him new books to read and shows him interesting places and things.

Well, that's my somewhat fanciful image of the Internet and related information technologies in the year 2010. In the interest of time I won't elaborate further on how we might use these tools in our work in the future; however, I do believe that their use in business and commerce will be pervasive, mainly because we won't have to be technologists to enjoy the tremendous benefits of the Internet and other information technologies I have tried to describe briefly for you this afternoon.

But that's enough of my views of the future. I thought I would close by showing you a brief video of what some real experts think about the Internet, and how they think they might use it in the future. Thank you very much.

Presentation

Girl: And if you're looking around the Internet, you'll find me at zero, which is not my I.Q. number. Well, the reason that the Internet has attracted many other people is because adults tend to like TV better, because the Internet involves, you know, everything. You know, it involves using your mind, which younger people tend to enjoy more than older people.

Boy: I never watch TV. It doesn't change my life, it's something to do when I'm bored. I'd rather do Internet because I get to actually be with my friends on Internet. And if I'm going fishing, I can only be with a couple of my friends, but on Internet I can be with all of them at once.

Boy: One thing I like about the Internet is the "call therapy" thing, because if you're just a kid and your friends are all into the Internet, and you would like to go explore it to see what it is and you ask your parents, "can we get a computer with a modem and a phone line hookup to get on the Internet?" and they say, "Oh, well, how much does it cost?" And you say a computer costs about \$1,500 and a modem costs some, they say, "No, that's way out of the price range for me."

Boy: There's a girl I know, and she has a boyfriend on the Internet. And I don't know if he's still her boyfriend, but as far as I know he could be completely ugly and yet he's her boyfriend because they talk to each other on the Internet. And they create posters on the Internet about, like, "Dynamite loves Sphere."

Girl: I just like talking to people. You know, people, because people say "hi" to me and they gave me some information, like about school. When I was in school I was having some trouble with the work and stuff, so I was talking to one person and he gave me some information on what I should do, and he said, "You are ahead of a lot of people because of your age, and anyone your age should be proud of that."

Boy: Our parents, they're used to using telephones and watching TV instead of using the telephone and TV sort of mixed together. My mom was the one who got the computer, but I'm the one who uses it mostly. She does business stuff on it, but she doesn't use the modem a lot. I was showing it to my parents last night and they weren't really interested; but of course this was like 10:00 o'clock at night.

Girl: The reason I like the Internet is because you get to create worlds of your own. You get to build up social skills and physical skills — your fingers get really tired, I have to tell you. But it's worth it. The Internet, you know; I mean, I laugh a lot. I mean, it's really funny because a lot of the stuff people say is funny, so if someone was watching me, they would see me giggle.

Boy: I think the Internet is going to go very commercialized soon because you can already see it happening and stuff. Like you can see a Web server somewhere where you can order a pizza or something — there's a Pizza Hut Web server somewhere, and you enter your home phone number and your name. So I think eventually the Internet is just going to become a big commercialized thing. Then they're just going to have to make a new network for public use.

Boy: For the guys who're the ARPANET pioneers, I have to say that they're pretty much geniuses, because 25 years ago no one would have ever thought of anything like this. But people, most people didn't even own a computer, so people would never have thought of computers through the phone lines. And I think to just even imagine that, not even to create it but even to imagine it, you have to be a genius.

Mark Lonergan: Just a brief story. It's interesting; my oldest son is about to enter high school, and he recently went to High School Night in northern California, and he was being presented to by five or six different high schools in the area that he had to choose from. And the first question — I mean, the adults all had the typical questions, how long is the school day, how much homework do they get — the very first question that all the kids wanted to know was, "tell me about your Internet access." Clearly, these kids are going to become the leaders in the future.

Before we get started on the question-and-answer segment of the meeting, let me take a minute to describe a couple of ground rules for the interactive portion of our event. In a unique symposium like this one, it might help if we added a couple of rules of engagement to help the process get started.

First, as my grandmother used to say, we're not here to sing duets and make fudge. There's a great deal riding on this phenomenon for all of us, audience and presenters alike, and

it is my duty to ensure that we engage constructively on some of those possibilities and explore as many of them as we can in the short amount of time that we have allotted.

Two, we're going to hope to keep the discussion at the 30,000-foot level; the better that we can talk, as the four of these gentlemen have already, about events in the future to give us some view of the context and the expectations for that time, I think the better we'll hope to serve you who attended this meeting today.

And then, finally, many of you in the audience, particularly the younger members in the audience, truly do represent the leaders-to-be in this important Internet world. With that much at stake, I encourage you to challenge these visionaries in their view of events to come in the audience participation segment, and we'll leave plenty of time for that at the end.

So let me start off — I guess I would like to throw open a question to any of the four panelists, and you can pick it up as it makes sense. It is interesting; I don't think I heard anybody during the discussion today talk about regulation or regulation issues as it relates to fifteen years from now. Any thoughts?

John Patrick: I think there are a lot of regulatory threats to the Internet, but I'm quite optimistic about this in the sense that I believe the industry can work on the issues that are the potential things to be regulated, and avoid the need for regulation.

I really don't see regulation as being helpful in any possible way. On the other hand, there are some real issues that have to be dealt with, so I think it is really incumbent upon all of us in the industry, while we may compete on many things, to cooperate on certain things. For example, in the area of pornography, [we need to] to devise technologies for content rating. There is some very important work going on at M.I.T. along those lines, and there's a working group of a number of companies, all competitors, working together to try to solve that problem. And I think as long as we coalesce around those key issues as an industry and focus on solutions, the need for regulation will go away.

Mark Lonergan: Anybody else?

A key question I had... I was talking to some friends not too long ago, one of whom is a stockbroker in northern California. The question that he had, given the topic and kind of the visibility that the Internet has gotten recently, is what kind of stocks should we consider putting into our IRAs in the year 1995? And perhaps even more importantly, what stocks should we be taking out? David, I'll let you start with that, since your stock seems to be doing so well.

David Garrison: I have an idea; I would put NETCOM stock in my kid's IRA! I would probably also — I think there is an interesting bias going on — John, you caused me to think about this. All computers will be connected to the Internet; I wonder if that isn't limiting, as a thought, because I think about computers together — some computers have keyboards, and that's the kind we tend to focus on here. But just as important are the smart chips, for example, when you slide your hotel room key in and pull it out. You know, that's a computer just as relevant to the average person — that is, the average person who happens to travel and stay in hotels — as is the computer with a keyboard.

The reason for saying that is I think that companies — perhaps like Intel, as long as they can leverage their lead in terms of economies of scale in chip development — will play a key role, because chips will be some of the applet building blocks we see in the future.

John Patrick: That's a very good point; all things with IP addresses [will be] connected to the Internet. When I say all the computers connected to the Internet, almost everything will have

an IP address: vending machines, your refrigerator, maybe toasters. We'll all have IP addresses, and that's what's going to make up the Internet, the interconnection of devices.

In terms of who to invest in, I don't know. I guess I think it's really hard to predict based on what people do today. I think it is going to be companies that are able to move fast and identify trends that will be possible because of the Internet, and who see the market. Those will be the companies that will prosper, I think.

Stephen Levy: Well, I would agree. There are going to be, as a result of the continued, rapid growth of the Internet and the fact that it makes small companies as visible as large companies, there's going to be a huge number of opportunities for companies that haven't even organized themselves today to be extraordinarily successful companies by the time we get to the year 2010. People who are building specialized databases are going to find a tremendous resource available to them through the Internet, a world that may want access to their databases. There are going to be people who are building and publishing all kinds of different services and helping figure out what it is that you would like to see, and publishing those as specialty groups, whether it be on travel or on the stock market.

There are obviously companies that are going to be building various kinds of hardware, communications companies that are going to over the next fifteen years continue to prosper as everybody fills out their information network. We have seen a number of examples of those already. Clearly a lot of the beneficiaries of the early work in networking have been the router manufacturers, and now we are starting to see other device manufacturers are prospering as a result of that.

So I think, from my own vantage point, that I see it as a wide-open world, and there are going to be many, many new companies that are going to be created; and given the way the venture capital world works and the IPOs work, I think we'll have a lot of opportunity to invest in those companies in the future.

Jay M. Tenenbaum: I think, realistically, that things are progressing in waves, and you had your opportunity in this past year to invest in the on-line service providers like NETCOM and BBN, who have also benefited during this year. We also saw the emergence of the companies that are providing the software for being able to access the Web at a base level, companies like Netscape and Spyglass. I think in the coming year we're going to see companies emerge whose job it is to kind of flesh out this infrastructure. We don't need necessarily more connectivity providers and Web browser companies; what we need are the companies that are going to deliver what it takes to make this stuff real.

And by "real," take the case, for example, of payment, which is something that I am going to be focusing on increasingly after my merger with Verifone. There are any number of payment solutions and none of them are really very compatible. You see the kind of competition that exists in the press between MasterCard and Visa to try to lock down the credit card standard. All of this stuff is going to be made invisible, not just to the consumer but the merchant, probably the bankers, or else they are going to just walk away from all this stuff.

So Verifone is going to spend a lot of time doing just what they did in the kind of countertop machines that you swipe your credit card through to get it authorized, namely to produce the software for the merchant and the consumer, and the bank that kind of pastes over the differences and complexities of all these standards. And the same thing needs to be done in every other field of the Internet to make the thing real. What we have seen largely up to today are neat demos of the potential of this stuff.

Take security as another example. It's one thing to have been able to demonstrate putting together RSA public key algorithms with Web servers in order to be able to show that

you can pass a credit card number more or less securely over the Net; but in order to make this stuff real on the scale that it's going to affect mass markets, we are going to need to see a whole infrastructure built up to be able to issue public key certificates that certify that you are who you say you are, and that are able to verify these things in real-time after each transaction, escrow them after you lose them and provide some kind of liability if you're not who you said you are. And on and on... These solutions are going to come from many different companies that are going to be fleshing out every angle, so there's going to be no end to investment opportunities. The one thing I would like to emphasize is that you should keep your eyes open as these trends start to emerge, and invest in the companies that look like they're making some progress.

Mark Lonergan: In the discussions that happened already, Marty, you talked a little bit about the fact that large companies, large communications carriers, are likely to bring us the Internet or to act as integrators in that. David, I thought you might have some ideas on that — unless you plan on being one of those large companies. How will the communications connection take place in the year 2010?

David Garrison: Mark, I think it is way too early to tell. Part of it is dependent upon the technologies that — for example, my son and I have addressed different devices so that we could remotely control our home devices and other things. That will in part determine the communications bandwidth that we need, which will in turn determine how it is we connect.

Isn't there massive consolidation happening? Won't NETCOM and other providers be wiped out by very large companies coming into the business? I think the answer is no. The key to this is not having a big balance sheet. I think the key is innovation and listening very carefully to the market, and being very flexible as the market proceeds. So 2010 and network? I don't know; we'll see. Ask me in 2009.

Mark Lonergan: By that time you might be buying U.S. West and seeing what it's like to live on the other side.

A couple more minutes and then we'll open it up for the audience. We'd love to have you participate; I'm guessing we've got some AT&T people in the crowd that might have some strong thoughts. Well, shall we do that? Let's do that now. Let me take a question from the audience, please.

M: I would like to ask a challenge part which relates to Mr. Tenenbaum's statement concerning the trend towards flat pricing. The challenge part is, I don't necessarily see a trend towards flat pricing. I see a lot of surcharges being applied to all sorts of different services, and that doesn't fall within what I would consider flat. And the question part is, your flat pricing trend that you're predicting, how do you feel that applies to intellectual property?

Jay M. Tenenbaum: I was talking about connectivity, for example. I think that for people who are going to tack on surcharges for things that relate to connectivity, they're simply going to get bypassed by people who are willing to provide pricing based on what the actual costs are.

But for this question we have two experts on the panel who are in the business, so I would yield to Steve and David to comment on it.

Stephen Levy: I agree with the gentleman who asked the question. I think that, as I said in my talk, pricing for content is going to change and we are going to start paying by the "click" for the kinds of services that we use. If we access a specialized service, we will start paying for that

service. And I would expect that in the near term, over the next couple of years, we will continue to see the cost of access decline.

I think I would agree with Marty that in that period of time we'll start to think of the connectivity as something like digital dial tone, where it's always there if I need it and I pay for it as I use it. But in the use of the Internet, we will continue to be able to do applications like electronic mail and publishing and so forth. But when we start to use services like entertainment services, games and specialized educational programs or specialized databases and so forth, we are going to be paying for that based upon what the vendor thinks that they are going to be able to extract as value for that.

David Garrison: I think that one of the things that we find over and over again, again coming back to customer behavior, is that customers like predictability. They don't like to be surprised and they don't like people looking for handouts everywhere they are. I think that one of the models we see, for example, is in cable television; we can just select the channels we want in cable TV. We could say, "I want CNN, I don't want the Weather Channel, I want this, I don't want that." But it becomes a commerce nightmare from the standpoint of billing.

What's happened in cable is very interesting. There are many people who will sell you services for ten bucks a month. As a practical matter, here in the U.S. specifically, people have selected two services, those being movie services, HBO and Cinemax and The Movie Channel. Depending on how you look at it, two horizontal services have survived out of all the services that can be ten dollars a month, and that is observation number one.

Observation number two is "connectivity provider." They say you guys at NETCOM will be a dial tone; I disagree. I think we are going to be a conduit and an intermediary between the content providers and the customer, just as a cable company is today. They bundle things into satellite tiers so you pay four bucks a month flat rate, and what you get is CNN and The Weather Channel, and you get products A, B, C, D and E. And we are seeing companies like InfoSeek offering services around pricing that tends to be 10 or 15 cents.

And I think the content providers will have to adopt flat rate pricing. I think that there will be aggregators who are not aggregators as we know them today, but distribution aggregators who will package that for customers and be the intermediary between different kinds of content providers and the customers who say, "Don't hold your hand out at every stop on this Internet stuff. I want predictable value. I want predictable pricing." I think we've seen this in other technologies and I think we'll see it in the Internet in the very near future.

John Patrick: I would like to add something to that as well. I think there is a tendency toward thinking of access or conductivity as just a simple thing that will become "commoditized," that it will be either free or there will be an Internet dial tone there for 50 cents a month or something. I think that's very misleading to think of it in such a simplistic fashion.

There is a range of things that go along from that dial tone to what people really want to do. A lot of that will be provided by various companies, BB&N and NETCOM to my left and right, ourselves at IBM, and many other global networks. People will find ways to deliver the value that customers want, particularly in the business environment. As companies use the Internet as a way to extend the networks they already have inside of their business, they are going to have a lot of demands that are not being met by anybody today.

I think the networks that exist in companies today, SNA, NetBIOS and IPX — there's many different kinds of networks and they're not going to go away for a long, long time, if ever; but they will be extended by the potential of the Internet. And as this extension occurs, there are going to be new classes of services companies. Today's Internet will not meet those needs.

It does not have the security nor the industrial-strength capabilities that business customers will demand.

So I think we will see a lot of innovation and a lot of escalation in the capabilities of the Internet, with redundant paths and with a merging of what we take for granted today as a simple router. You know, just plug in a router and connect it to the Net. Routers are going to become very sophisticated in the future, and certainly by the year 2010 routers will be blurred with servers, and firewall and multimedia capabilities will be part of those routers. It's all going to come together in a very sophisticated server that will enable the business customers of the world to reach out and connect their existing networks to a much broader constituency than possible today.

Stephen Levy: I think John and Dave make a very, very good point. The focus of this panel has been on the year 2010 and what the world might look like in the year 2010. However, the world doesn't look that way right now. Our company, our Internet service provider, BBN Planet, provides services principally to businesses, not to individuals, and what businesses have is very, very complex network communications systems in place already. They are distributed all over the world, and there are all manner of networks that have to be connected together. It's going to take many years to rationalize that complexity.

And that's the service that an Internet service provider such as ours can provide today to those businesses, to rationalize that complexity for them, to interconnect many of their dissimilar networks and ultimately to connect that up to what we think of as this ubiquitous Internet today.

And that is very complex. It requires network management skills, network integration skills, the ability to run Web sites, large Web sites, and the ability to deal with foreign PT&Ts around the world. We think we have a "U.S.-centric" view of the world, of the Internet, but the rest of the world is not as far along in terms of the use of the Internet, although it is coming along quickly. If one views it as a multinational company, one views the needs of a multinational company as having offices all over the world; those offices are connected by many PT&Ts and many networks, and the service provider has to rationalize all of that for his multinational customer.

David Garrison: If I can add just one comment to that, regarding copyright. Our company, as some of you may know, is currently being sued over the activities of a customer of a BBS where the BBS was then a customer of NETCOM, and some of the information that that person allegedly put up on the service allegedly violated copyright laws, et cetera, et cetera, et cetera. We are being accused of being liable for violating the copyright laws, which we strongly disagree with.

The issue here is much like if you were running a restaurant, and you would have to bug every table and listen to every conversation being held, and if any slander or libel occurred [you'd have to] run around and go issue a ticket to the person and say, "I'm sorry, you have to leave my restaurant right now because you just slandered somebody, because I am the controller of all information."

And we believe that, at the core, that is exactly what the Internet is not. I can't control all individuals. I will enforce known copyright violations. I will enforce it if I know that it is happening, if it is a persistent violation; but I think what we are being asked to do in this lawsuit is a challenge to the freedom of the Internet, and I think it is a challenge to the way that this technology will evolve.

I think very strongly about copyright, so I didn't want to let that question go by without offering that thought.

M: It sounds like the model that you have all talked about is one of special-interest providers putting packages of content together. On the other hand, if you look at literature, the paradigm in literature is really the library system. So imagine a Dewey Decimal System, if you will, for IP addresses, where that morass of information that's out there, that chaos, is put under some amount of control so that people can do reasonable searches on it instead of that provided by a special-interest content provider. What do you think would be the impact of some type of global approach to organizing information?

David Garrison: Bring it on! It would make it much easier for customers.

Jay M. Tenenbaum: I think the wonder of the Internet is that, "who knows?" But why don't you go try it; it won't cost you all that much to get started.

Personally, I think that what will happen, actually, is that it's likely to happen not in the sense of a centralized Dewey Decimal System, and not in the sense of a centralized directory like a *Yahoo*, either. I think what's going to happen over the coming years is that we are going to see lots of specialty organizers of information [working] in areas of content that they care about, doing a very careful job of organizing things that are meaningful in one field or another, and they will charge people for access to those services. Or maybe they will use that as a way to bring in users from a particular community and then be able to turn around and sell to national advertisers who want to reach that community. This is just another example of an aggregator, in a sense.

So, by all means, go do it. I think Dewey Decimal in particular is much too limiting for the dimensionality that we are talking about here; it's a much more complex space.

John Patrick: I see it that way also. It's hard to imagine a Dewey Decimal System for everything on the Internet. That would be basically a cataloging of all information, and I'm not really sure how useful that would be; I think it is a lot more useful to have communities of interest that provide value to people around that community. Take something simple, for example, like one of my favorite sites, the "Micro-brewery and Brew Pub Guide to the Internet." Somebody who's interested in beer has created a site where he has catalogued micro-breweries and brew pubs around the world. Well, that's really valuable to people who are interested in beer, but it is certainly not something that probably would fit in the context of a Dewey Decimal System indexing of all information in the world.

I think the brew pub thing is a more likely valuable kind of a thing than trying to index all information.

Jay M. Tenenbaum: There will be an ecology of these things. Someone will do brew pub and someone else will care about restaurants, you know, and he may point to these things. It will be a big mass ecology, and that's what the Internet is about.

M: It's an interesting sort of dichotomy coming out here. At one point I was hearing disintermediation, and then at another point I was hearing reintermediation. We're going to have new intermediaries. Maybe we could just open up for a bit of discussion among the panelists. Who, in their opinion, may be the first ones or the ones they see being disintermediated, and what new intermediaries do you see coming in the future? Sort of what Marty was saying in his talk, and some of the comments David has just made. Maybe we could just generate a little discussion around this.

Jay M. Tenenbaum: This is getting directly to my comment about danger juxtaposed with opportunity. The point is that anyone who is an intermediary today is in danger of being bypassed. And virtually everyone, at the same point — if they understand what's happening right there — has the ability to be able to gather much more market share globally than they ever had before. That really is why it's very important to get plugged into what's happening, to go visit sites like CommerceNet, for example, which is an organization I have had something to do with, which is trying to just open the eyes of the members to what these dangers and opportunities are.

Mark Lonergan: That raises an interesting question. A couple of you referred to the fact that companies can be started and run almost like virtual corporations with entry and dropout varying dramatically. A question I would like to hear you talk about is, what are the sustainable competitive advantages that people are going to be able to use to hold on through the Internet? In other words, how do you use the Internet, if you're already a business that is thriving, to sustain that competitive advantage without worrying about the new guy in?

John Patrick: I'll take a crack at that. I don't think there's anything that is really sustainable; I mean, this is a technology which enables anybody to get into any business from anywhere, so nobody can be comfortable in the business that they're in and think that it's going to be sustainable unless they are evolving with the Internet very rapidly. Disintermediation is going to happen, and it will happen by necessity because the Internet makes it possible to happen. The technology makes it possible.

I might differ slightly, Dave, with your point about the idea that technology doesn't drive it. I think in many cases technology does drive it, because if it can happen, it will happen. And as soon as somebody does it, if everybody else doesn't do it or do it better they're going to be on the outside looking in.

I think businesses today, in terms of what this means for them, it means they've got to get connected. A business without a viable, compelling presence on the Web will very shortly, in months, be like a business with no fax machine: they won't be a business. And so it's not a matter of whether this disintermediation is going to happen; it's going to happen. You've got to get out there and get connected. If you're in one of those middleman roles, you have to redefine your role and find a way to provide value.

And I think the way businesses will do it is by extending their reach. From my point of view this is all a matter of reach, reaching constituencies that you couldn't reach before and using the Web in effect as a GUI into existing business systems, so that whereas today you're limited by whatever kind of a computer you have and whatever kind of protocol your terminals or PCs use to connect to that computer, that's going to become irrelevant. The Web will allow any person with any kind of a browser to be able to come into your business system and get the information you want them to get. It's a great opportunity.

David Garrison: Marty had commented before about the death of distribution monopolies. I think that is particularly true as it relates to information; but as far as physical products are concerned I would probably differ. I'm just trying to think about my own life, and what I buy. In most cases, for everyday purchases, I think the cost of transportation will be so great that we will maintain what we know today as "physical aggregation places," or stores, the K-Marts and the Wal-Marts of the world. The brands may change and the goods may change, but the cost of transportation means that it will be a significant issue. Even if I could order it through the Net, the cost of transportation, I think, will be significant enough that I won't get it delivered one-off.

Stephen Levy: That's true, Dave, of physical goods. But if you think of services like travel services, there isn't really any reason to go to a travel agent to have Net travel services done.

David Garrison: I agree.

Stephen Levy: Or a bank. Or think of entertainment; there will be no reason in the future to go to a video store to get the movie that you want to watch.

David Garrison: Or to this conference.

Stephen Levy: That's right!

Jay M. Tenenbaum: That's not so good for all these hotels and restaurants, is it?

But one thing you did say, you said Wal-Mart. Sure, physical distribution is going to be very important, and yet if everyone is on the Net, it is going to be relatively easy for suppliers to offer the kinds of services to small merchants that today Wal-Mart demands and gets because they invest \$12 million a year in their private satellite network. Companies on the Net, suppliers on the Net, can manage the inventory of a small mom-and-pop just like they can Wal-Mart, and so I don't think Wal-Mart's position is necessarily safe.

Mark Lonergan: Let me see if I can help repeat the questions just so everyone can hear. In the back? Did you have a question?

M: Yes. Can you relate to the Internet how some of these future technologies might relate to it? The technologies would be cellular technology, PCS or personal communication services, PDA or personal digital assistants, and low-Earth orbit satellites.

Mark Lonergan: The question was how do these various technologies relate to the Internet — PCS, cellular, low-orbit satellite, and PDAs. Who would like to take a stab at that?

John Patrick: I will. I think it is not really that complex. All the devices that you mentioned will have an IP address and a browser — or whatever we call it fifteen years from now — and they will have the fundamental ability to participate in viewing and accessing information that is available on the Web. And in terms of all the LEOS and cellular and other forms of communications, they will all be mechanisms by which the IP communications will be facilitated. Today there are a lot of ways to be able to connect, and there will be more ways in the future. And I think it's very hard to predict what the growth rates of them individually will be; perhaps Steve will have some thoughts on that.

But from my point of view it really doesn't make a lot of difference. What's important is that we will all have access somehow. And if we live in the jungle somewhere, perhaps satellite will be the most appropriate for us. If we live in this country, I suspect cable modems will become fairly popular. But it really doesn't matter; you will have the bandwidth you need to be able to participate in this phenomenon and all of the devices, from a PDA to a cellular phone, to your car, to a supercomputer and everything in between, will have an address and will be part of this network.

Stephen Levy: As they are to some extent today. I mean, many of us access the network using a cellular phone. When I was preparing this talk I sent out an e-mail to a number of people at BB&N who I think of as forward-thinkers. We have a lot of technologists and are doing a lot of

research on a number of the topics that I mentioned during the course of my talk. And sure enough, as I look down some of the notes that came back, one of my colleagues says “PCS, low-Earth orbit satellites and HDTV will all be combined and used in the Internet.” He describes something about when you’re in a place of business, PCSs will allow local access to nanocells as you move from meeting room to meeting room.

And I think I agree with John, that as long as these things have an address, as long as they have utility, they will be used and they will be connected to the network and they will have a role in the network.

Jay M. Tenenbaum: The one thing I would add to that is that with wireless devices, one difference is that these might not be connected continuously to the network, and that is going to open the way for the kinds of agents that people like General Magic and others talk about, that will basically watch out for your interests on the Net while you’re personally disconnected, and of course contact you, buzz you, when there’s something you do need to pay attention to, according to rules that you yourself set down for those agents.

Mark Lonergan: Question here in the front.

M: I had a question with regards to — we’ve been talking about the future, and our youth is drawn to the Internet. I don’t think we teach COBOL or CICS or IMS in colleges anymore. We run literally hundreds and millions and hundreds of millions of lines of code on legacy systems. If you don’t train your people, they leave. If you do train your people, they leave. The FAA is falling apart because they can’t keep their air traffic control systems running. The Federal Reserve runs on legacy systems most of the financial institutions in the world run on legacy systems, and I can’t keep people interested in working on legacy systems. Can you guys talk to that a little bit? Because we’re talking about the social impact of this whole mood.

Mark Lonergan: So the question is, with all the focus on future issues, how do you keep the old stuff working?

John Patrick: Yes, I think this is a really important point. The solution to this, I think, lies in the ability to combine legacy languages with new-object technology and to be able to encapsulate those modules of code that were written in COBOL or assembler or RPG or whatever, and to be able to encapsulate these modules of code from the past and determine what that module does, put a wrapper around it and incorporate it as an object and enable it to interact with new objects that were created using C++ or Java or visual aids or various things.

This has been the approach that we have been working on, to try to incorporate those legacy modules into an object framework and allow them to be carried forward. Eventually they become irrelevant; but, as we all know, it takes many, many, many years for some of those modules to go away. I think it’s a very excellent point.

Stephen Levy: I was going to say that in working with a number of businesses, to make this transition, you have to have a transition plan. You’re addressing the human element — you know, how do you keep people interested in supporting systems that are viewed by their colleagues as perhaps archaic and not in the mainstream? And I think this gets to the whole question of lifelong learning, and how you keep people trained, how you develop transition plans to go to new technology. Because clearly, if you’re running those systems — and you mention the Federal Reserve; I was on a project at Federal Reserve where we were looking at transitioning to new systems — and if you’re running those systems, they have to be kept

running, but you also have to start thinking about how to take advantage of new systems and entirely new processes, business processes that are now made feasible by new technologies.

We have one customer that's doing two-thirds of their customer service, a very large company doing two-thirds of their customer service over the Internet. Obviously, a few years ago they weren't doing any of their service over the Internet; now they are saving five million dollars a year in labor costs and improving their customer satisfaction. They have had their customer satisfaction independently tested, measured, and they are improving their customer satisfaction by 30%. Now, if their competitor is mired in old systems and doesn't have a transition plan to train the people and to transition those systems, then they're doing a disservice to their employees and their shareholders by not doing that.

Jay M. Tenenbaum: I think I will underscore a point you just made. The question as you posed had, I think, a certain defensive ring to it, and I would like to urge you to think offensively. What the Net opens up for the first time is the possibility of taking these legacy systems, unlocking them and making them available by being able to put them on the Web. The Web is not just Web servers, it's databases and whatever, and you want to put those on the Web in a way that can guarantee the security of the information that is in there. You would like to provide access to those who are authorized to get it, and it might be customers, certain customers or employees or certain suppliers. And that opens up all kinds of new opportunities in the direction of the business processes Steve talked about.

So you can get people who are associated with legacy systems really fired up by this stuff, and that is what I would urge everyone to do.

Mark Lonergan: Looking at the time, it looks like we've got time for a couple or three more questions. Why don't we take one from over here?

M: If the model is conceptually one where ownership is by private and public institutions, the concept of a flat fee in the future goes against other things that you have to charge for a packet that goes on the Internet, because somebody has to maintain it and provide it.

Mark Lonergan: So the question is, how can you afford an Internet when you've got a flat fee structure to pay for it? Anyone want to take a whack at that?

David Garrison: In the short term I think flat fees will be what is required from a customer viewpoint. But I think those flat fees are really going to vary based on usage patterns and perhaps on the size of the pipe, as had been suggested before. I think that there will have to be eventually some sort of settlement process, if in fact there are non-profits that continue to support large pieces of the backbone. If those do not shift to for-profits, or if it's terribly unbalanced, there will be some settlement process, just as we have seen, for example, in the early days of the long-distance business. But I think the flat fees are going to be required to make it acceptable for customers.

Mark Lonergan: There was another hand up here in the corner.

John Patrick: If I could just add one little point to that. I think, on this notion of settlements, that a lot of people are beginning to say maybe we do need settlements. You may be right about this, Dave. I'm not so sure. But I think the Internet is moving much faster than a settlements process could get its act together. The process of settlements is a complex thing to do. Who's

going to figure out how to do it? And by the time people get together and figure out how it's going to work, we will have moved to the next plateau of networking.

Personally, I don't see settlements coming into the picture in the traditional sense. Maybe Steve would have a different view.

Stephen Levy: No, I would agree it is very complex, and what we are really running today is a number of parallel networks allowing one another to pass traffic over each others' networks. So the real beneficiary of a non-settlement approach is the small providers, who are getting a free ride right now.

David Garrison: I would suggest, though, that settlements are a solution if a person or an organization who is providing a major piece of the backbone feels great pain. That's the only reason why the whole settlement process would start. But if they don't provide an irreplaceable piece, then it's not going to happen.

Stephen Levy: Well, clearly this becomes a greater issue as the costs of running the network and the backbone portion of the network increases as we start passing video traffic over the network, and the bandwidth goes up and we need very much larger, more expensive pipes and switches connected to it.

John Patrick: That's really the point Steve just made. People will demand levels of service far beyond what is possible today, multimedia being probably the key driver of this. And this demand that they will have will cause companies like Steve's and mine and others to invest and to develop new technology and build bigger pipes and better pipes and better network management tools and capabilities. And all of these things will be economically viable if people will pay for them. So I think we should be sanguine about the future of this.

Mark Lonergan: Question over here.

M: As businesses, the idea for many years has been to push our products or our information out to users. It's a pushing structure. In the future when everybody is connected, it's more going to turn around and it's going to be a pulling kind of structure, where the user is going to decide what he's looking for. How are we as businesses going to even exist? Or how do we make sure that people, after they're all connected and they don't read our ads in any magazines because there are not going to be any magazines, how are we going to make sure that they know what's going on? How are we going to run a commercial when they can switch channels and go to something that doesn't have a commercial, to make sure that they're not missing the information that's being pushed onto them?

Mark Lonergan: Just to repeat the question for a moment, the question is, how do you maintain the interest of the consumer when the consumer has control over the communications medium?

John Patrick: This is an inversion of the publishing model, right? Today editors and publishers decide what you and I are interested in, when we're interested in it and the degree to which we want to go into the subject matter. That model will invert completely. It already has, just as you posed in your question. This is good for you and me. This is good! Now, businesses just have to be responsive and have to create compelling content and provide value in their Home Pages.

There's 30 million Home Pages out there. Why are they going to come back to your page or my page? Because there's some value there.

Now, if you go into various publications today you'll see what are the most popular pages — the top ten. Why should ten pages be so popular when there's 30 million of them out there? Well, somebody figured out how to create some value there. You go there because you want to download something or because there is a point of view. People will still be interested in a point of view from experts.

So I think there are many ways that content can be differentiated and can be made interesting and compelling, humorous and so on, and people will come back and businesses will distinguish themselves by being very clever at how they do this.

Jay M. Tenenbaum: And don't think for a minute that advertising in the mass media is going to go away. In fact, just the other night I saw, for me, the first national ad on a television network which had a phone number and then a URL underneath it. And it didn't say Internet on it; it just had the thing. And I can imagine someone calling up the telephone operator and saying, "How do I dial this colon slash-slash thing?"

David Garrison: One other comment on advertising. I think that advertising will be very much a part of the Net, but it will be much more sophisticated, much smarter advertising, more in an infomercial vein where the customer will control what information they get and how they get it. I look at television, which we suppose is free in the United States, and if I remember the number correctly, the average American citizen pays about \$128 a year for television for the advertising spent by the people who make the goods that the customer purchases.

Follow me through on that. You see a cable bill, an average cable bill of maybe \$28 or \$29, but the average American is spending about \$128 on TV. And I think you will see some characteristics on the Net where the cost of access and other services will go down and be paid much more by advertising, but in a very different paradigm. We haven't seen advertising on the Net yet the way it will be. It's coming, though.

Mark Lonergan: Why don't we take one more question. Someone else? Here we go.

M: The personal privacy issue. When everything has an IP address and all our devices are connected, how do we guard against unwanted entry?

Mark Lonergan: So the question is, how do you protect confidentiality and privacy in a world where your toaster has an IP address? John, I'll let you start with that.

John Patrick: Well, I think there is a temptation for people to think of security as a problem when really we should think of security as an opportunity. And in fact encryption will, without a doubt, provide a level of privacy far better than what we have today. Far better.

We walk into the hotel down here, the Marriott Long Wharf, and the first thing they say to us is, "How are you going to pay for your bill?" And we hand our credit card to a complete stranger. We call Lands End and we give them our name and address and our credit card and date of expiration, and we think nothing of it.

It's going to be a lot better than that on the Internet. This public key technology is a magical, wonderful thing, and it works. And in spite of what you have read in the paper, nobody has ever broken a full-strength encryption key. They've broken some weak ones that the U.S. government allowed to be exported so they could be sure they could break it; but a real key has never been broken, and keys will only get better in the future.

And so privacy is going to be far, far better. Think, just for a second, about the world of the certified letter. We do this all the time. We put something that is of vital security and sensitivity to us in an envelope, and how do we protect it? We mark it, your eyes only, top secret, to be opened by addressee only. There's a powerful protocol, right? And then what do we do with that envelope? We hand it to somebody in the mailroom. Have you interviewed the people in your mailroom lately? And what does that person do with it? They give it to a person in another mailroom. Well, who actually opens that envelope? We have no idea.

Now, just think for a minute what we're going to have on the Internet. We have it today, right? You have something secret you want to send to another person. You'll get that person's public key from a certificate authority, and you'll be comfortable it's really their key; you'll scramble this letter to that person with their public key and you'll sign it with your private key; you'll put it in a cryptographically sealed envelope and you'll whisk it across the Internet to that person. And when they open it with their private key, you will know that only they could have opened it; they will know that only you could have sent it. You could not have been "spoofed." And when they look at your digital signature, they'll know that it was really you. And another by-product of this is that there's non-repudiation; the person can never say, "I didn't get it." Okay?

So this is security far beyond what we have in the real physical world today, and it is more private. Privacy will be enhanced by the Internet, not to worry. And firewalls work also.

Mark Lonergan: Anyone else?

Well, I tell you, let's call a close to it there. I never expected, in putting this group together, that we could get this much accomplished, and I really appreciate the efforts of the four leaders who have joined us today to get this process started.

I would like to thank the four of you, starting with Marty Tenenbaum, Steve Levy, John Patrick and David Garrison. You folks made this exciting and fun. Thanks.

Also, I would also like to thank Alan Meckler and Nancy Nelson. Alan, of course, is the President and Founder of Mecklermedia, and Nancy is the General Manager in charge of this show. I appreciate the opportunity to present in front of you. It's been terrific.

And finally, and certainly most importantly, I would like to thank you, the members of the audience. By being here, by contributing your questions — and clearly, your passion — you have made this a worthwhile session, and I appreciate your attending.

Thank you for coming and please enjoy the rest of the conference.

ADVERTISING FORUM ON-LINE AND INTERNET COMMERCE — WHERE THE LINES CONVERGE

MODERATOR

Vice President, Executive Editor, Adweek Magazines

SPEAKERS

Andrew Nibley

Editor, Executive Vice President, Reuters New Media, Inc.

Jay Sandom

President, Einstein & Sandom

Leslie Laredo

Director, Advertising Development, AT&T Interchange

Jay Sandom: Hi, I'm Jay Sandom. I'd like to thank you all for coming here today to talk about what's going on in this exciting new area of interactive communications on-line. Unfortunately, I was not able to hook up in time to go live, but I did can some screens so I will be able to show you some of the things that we've been doing on the Web. Hopefully, by the next speaker, it will be active so you'll actually be able to go live. Given that, however, at the end of the presentation I will invite anybody who would like to come up and give me your card. I'll make sure you get URLs for all the sites we've built in the past and the other commercial on-line services work we've been doing so you can take a look at it yourself at your leisure.

Just to give you a little background on who we are: as you heard, we were founded in 1984 and, indeed, we were the first interactive advertising agency in the business. When we first started, multimedia marketing and multimedia advertising was basically you buy a print spot, you buy a TV spot and that was basically multimedia. Clearly we've gone a long way since then.

Our company is structured in three divisions. One is the multimedia marketing division where we develop strategies on behalf of our clients; usually they're large Fortune 500-type organizations, or we work with a number of different advertising agencies to help them form multimedia and interactive multimedia marketing strategies for their clients. We also serve as a production company in developing actual "inter-ads," or interactive ads, and other multimedia marketing communications applications.

Secondly, we have a computer-based training division, and for some of our work where we're dealing with, for example, direct sales forces, we will create a computer-based training application first and foremost to train that remote sales force in how to sell their new product in the field. Then we'll use a lot of that same digital content and re-purpose it in order to create multimedia marketing applications.

Lastly, we have a title development division, which is a new element in our business where we're actually creating some shrink-wrap products for sale to consumers, with a focus on entertainment-based products.

Just to give you a sense of the kind of clients that we have — which I think is indicative of which industries have now really started to adapt and really embrace these technologies — we first began in a high technology community. One of our first pieces was done for Compaq, for their first Compaq LTE. We came out of the demo disk business originally, but since then we've seen a real broadening of the kinds of clients that are involving themselves with these kinds of technologies, whether it's financial services organizations, automotive, pharmaceutical or, in the last two years, packaged goods.

We have a representative from the Four A's. I don't know how many of you were down a couple of years ago when Ed Artz made his seminal speech about interactive advertising, but in a nutshell Ed Artz, Chairman of P&G said, "If we don't figure out a way of selling some of our packaged goods such as toilet paper and other rather mundane products in an interactive universe, then we're all going to be looking for a job." That was really a rallying cry for a lot of ad agencies to get involved with this business. Many of them — little interactive advertising groups within their organizations — have gone out and acquired independent companies such as ourselves to develop these kinds of technologies on behalf of their clients.

I'd like to show a few case studies, because I think this is indicative of what's available to us. While we're going to be focusing today on the on-line universe, I'd just like to point out that we work and have worked in a number of other digital channels as well, including disk-based which was the original delivery channel back ten years ago in sending diskettes via direct mail to customers.

First example: one of our first clients is Citibank, and we've been promoting some of their financial services using diskettes as an electronic brochure. We also do a lot of work in CD-ROMs, whether that is a dedicated CD-ROM for one particular advertiser — for example, right now we're working on a CD-ROM for Pontiac to showcase all of their cars — or whether it's working with the "digizines" that are out there today and growing by leaps and bounds.

[With] the CD-ROM-based magazines we will create interactive advertising to insert in those digizines as well. We also work in the kiosk area in developing point-of-information and point-of-purchase kiosks for trade shows and retail outlets, corporate high-traffic areas.

Lastly, as you sort of look at broadening the bandwidth all the way up to interactive television, we've been working with a number of the different ITV providers that are in test today and consulting with them on how to develop their models — not only the technologies, but really what is the taxonomy of their service, what is the pricing model, etc.

Today, however, we're focusing more exclusively on the on-line services and the Internet, so I'd like to sort of walk through those since we only have a few minutes here today. Three examples of clients we have worked with in the past are Hyatt Hotels, Australia for Australia tourism and the American Plastics Council, which is a site we recently completed on the Web.

In the case of Hyatt, and in speaking about the commercial on-line services versus the WorldWide Web, we believe that if you're in the advertising community you can select radio, print, a number of magazines, a number of radio stations or a number of TV shows in which to place your advertising content. We believe you're really doing your clients a disservice if you focus exclusively on the Web. That has become the kind of "flavor du jour," as ITV was a couple of years ago, and we believe it's very important for clients to look at the full panoply of digital channels out there, not just on-line but within that on-line universe, [with] the commercial on-line services that in many cases have a much more established audience and much better demographic profile of information about the targets you're trying to reach.

In this particular case of Hyatt Hotels we were looking to target mostly for business travelers. Again, a business-to-business application. We targeted business travelers who traveled internationally with the information they needed in order to promote Hyatt Hotels.

We wanted to give them the ability to speak directly to Hyatt, and to collect data about travelers and their travel habits. As you may know, for reasons of privacy the commercial on-line services will not provide you with individual names unless the individual who is accessing their on-line service volunteers this information, but they do provide a lot of information in the aggregate form which can be very helpful to us.

In this particular case, our solution was to build a store in the electronic mall. We have three million members worldwide on CompuServe, and 30% of them are overseas. Our clients

obviously have a lot of properties overseas, so rather than AOL or Prodigy or some of these other commercial on-line services, we chose CompuServe for their large percentage of business users. We developed a store that had the ability for the user to visit Hyatts worldwide, to access their worldwide guide and to join their "Go Passport" program, which is their frequent-stayer program.

We also developed a search engine that helped them to access properties based on a number of attributes; so if they were looking for a golf course in Southern France so the chairman could play golf during his convention, you would be able to put in those attributes and come up with a property that you wanted — a virtual concierge that allows travelers to speak directly to Hyatt and offers the ability to book directly for reservations. This is what CompuServe looks like, and you can see that we were able to place this Hyatt Hotel right next to Easysaver, which is one of the most highly accessed areas on CompuServe. You can see on the right that you can do a number of things with this site — you go and look at the resorts, join the Passport Club, get specials, exclusive CompuServe packages and a number of other things.

One of the search engines that we developed for people going in to look at properties included a feature where you could select a property based on physical challenges or art and culture. If you're looking for water sports, for golf or tennis or any number of various other attributes, you could select those to pick the property.

In this particular case, [for this demonstration on the screen right now], we were looking for fly fishing in Argentina. We have some specifications on the hotel, and you can download a picture file to look at the property itself.

The results of this campaign in September/October period [were that] we had 65,000 hits at this site — and these are actual members going in, not just the same guy accessing it several times. We were able to sign up 1,000 Go Passport applications. We had 700 other people order brochures, 600 special rate requests and over 300 miscellaneous inquiries. So this proved to be a very successful campaign on CompuServe because it was very targeted. We looked at the kinds of application needs this particular business traveler wanted, and we were able to deliver it via the technology that CompuServe provides.

We move on now to a different challenge, which was a consumer campaign targeting individuals. In essence, Australia was a client that [hired us] to enhance awareness of Australia as a premium travel destination. We also wanted to showcase the texts and photos, the top tourist destinations, to provide Australia files with the means to communicate with one another and build a community.

You all may know that one of the major reasons that people go on-line with the commercial on-line services like AOL, as well as the Web — 50% of the members say that the top reason is to chat, to talk with one another in this virtual community that various cultures create, so that was one thing that we wanted to provide. We also wanted to deliver on-line conferences with Australian celebrities and to highlight special tours.

Our solution in this case was not CompuServe but America Online, the fastest growing of the commercial on-line services and [the one with] the largest membership base domestically. They have a rather large and expensive — you may have seen this package slammed in the media in the past, the \$240,000 media buy for AOL to develop a full domain. Ours is one of the few dissenting voices. In looking at that particular offer, we felt that if you look at the content and the amount of content you could get for that media buy. we felt compared to Prodigy, for example, and that it was actually a very good deal.

So that's one way you can go at it. The other way, of course, is to negotiate with a content provider or an editorial entity on AOL. We chose a third route in this particular case; we negotiated directly with "Travelers Corner," which posts the travel section on AOL and will

soon be hosting a travel section on a number of other services. It does right now on *Pathfinder*, for example, on the Web. This was a less expensive route and also provided us with the same kind of content capabilities that we wanted to exploit. We offered a free sweepstakes for people to travel to Australia.

We partnered with one of the prime Australian tour operators to offer specific packages and we negotiated, I'm happy to say, with a number of Australian celebrities, including Elle McPherson who will be going on live next month. So if you want to go on-line with Elle McPherson you can find out about the hot spot in Sidney, or the best nude beach and whatever it is you're interested in.

This is what it looks like on AOL; [it's] considerably more colorful than CompuServe. Since it is a consumer-based service, you can communicate with a number of different individuals as well as Australia [and get] a variety of travel tips based on what it is you want to do when you're over there. It offers you information on special tours, the contests, and enables you to actually sign up and win a free trip to Australia if you're lucky. We've developed a number of utilities that you could access live or download so you wouldn't have to suffer the on-line charges here in order to build your own itinerary if you're traveling anywhere in the world, and not just to Australia.

You could go in and get information about Australia, as well as picture files. If you're interested in Tasmania — or trout fishing, since I seem to be obsessed with trout fishing these days — you could go and find out about Tasmania and what was available there.

The results in this particular case: we had over 16,000 entries in the sweepstakes in the first two weeks of going live. In the first month we had 55,000 members going into the virtual Australia domain; 25,000 images were downloaded; and in that time 500 utilities were downloaded.

Because of the high traffic we generated at this particular site, AOL placed us on their "Banner Page" three times in the first month. This was a real coup. As you know, it's one thing to have a great site — whether it's a commercial on-line service or the Web — but it's another thing to drive traffic into that site. So negotiating these kinds of promotional deals with these providers is very important to developing what we call "cybersignage" in driving traffic into the site.

Talking about the Web, we believe that cybersignage is really critical. The commercial on-line service already has built-in constituencies; clearly the Web is a different animal all together. It's like having a party — you can have the best caterer, the best bartender, the best band, but if nobody knows about it, who cares? So driving traffic in there is really key.

In developing a site we look at a number of different vehicles in promoting the site and driving in traffic.

Starting from the top and working clockwise, we often negotiate with sympathetic WorldWide Web corporate domains and ask them to develop a link so that if traffic goes to their site they can bounce directly from their site into our site. These days, sometimes you have to pay, sometimes you don't. It's still early enough in the game where very often reciprocity works — you know, "we'll give you a link to ours if you give us a link to yours." Another thing would be sympathetic editorial contents on the Web where you would be able to buy, for example, a space in one of the editorial providers there.

Time Warner would have you on *Pathfinder* on the Web, and develop a link directly into your Web site. Passive media, TV print, radio ads, business cards, any number of different vehicles or passive vehicles where you can promote your URL or your address on the Web should not be overlooked; and, of course, [you should look at] the on-line services, the commercial on-line services. Not only do they provide an established constituency base, but these days they also have very robust browser links, some more than others. But they all have

browser links from the commercial on-line service, so if you bring them into your site on Prodigy, CompuServe, MSN or any of these other services like AT&T Interchange, you will be able to jump directly from there into your Web site.

Lastly, let's not overlook sympathetic "digizines," [which are], again, CD-ROM-based magazines where you can develop a little button on the screen, and if that has a modem you simply click on it and it automatically dials the phone and brings them into your Web site. So these are all different ways that you can leverage these other constituency bases and actually move them into your Web site.

I'd like to talk a little bit about this last case study, which is the American Plastics Council. We've done a number of Web sites for Pontiac, for Cadillac and Kraft and a number of others, but this is one of our more recent ones and it exploits something which we're very proud of and something which is very unique on the Internet today. Our challenge in this particular case was to develop a site for the American Plastics Council targeting a variety of constituencies which are very key: academic students, industry members and others. Our solution was to annex that site on our server. In some cases our clients have their own server, but very often we encourage them to lease some space on our server. We exploited something which we call "Charlie," which stands for "Customized HTML and Real Prime Link Integration Engine." That's why we call it Charlie — it's a lot simpler.

We also wanted to position the site as the definitive location to find information about plastics in the environment, and we wanted to propagate the site with a lot of archive articles and other information about plastics in the environment. Finally, we negotiated on behalf of ABC with a number of very sympathetic sites for cybersignage to make sure that people would know where we were so they could come in.

I'll talk just a moment about Charlie here before I close. One of the biggest problems on the Web — as we've seen it on working on the Web for the last year or so — that's two years, really — has been that if you go in as individuals to any given Web site, to a Home Page. Generally speaking, unlike other digital delivery like discs and CD-ROMs and kiosks, which are robust enough to personalize themselves based on individual accesses and based on the needs of that individual looking at that particular site, the problem has been in the past that you go into a Home Page, it's the same Home Page for everybody; and that does not live up to the promise of interactivity, which is really the power of one-to-one relationship marketing and what this is all about.

So for the last year and a half we've been putting together and working in units to develop a database engine which we call "Charlie," which sits behind any given Home Page and provides you with benefits. It allows you to capture data about each user to detail profiles; that is, when somebody comes into a Web site, they're not forced, but we ask them to give us a password so that we can identify them as an individual, and that enables us to track every keystroke they do with our disk-based, CD ROM-based and kiosk-based applications. We know how many modules they go into, which modules they look at and how long they spend in those modules, [and we do this] for accountability sake so we can learn and improve our site over time. It gives us a very clear picture of each individual that enters the site because every time that individual goes in it enhances the personality profile that is unique to that individual.

In the case of Pontiac, for example, we had one guy going in, and he likes red sports cars with convertible tops and wind in his hair and what have you. The next person may like a large kind of car with elegant features and really doesn't care about the engine that much, but cares more about the rich Corinthian leather and the sound system. We need to know that if we're going to target these individuals effectively, so tracking where they go within these sites is very important. Once we know that it also allows us to build that personality profile, to pro-actively market new products and services and information with e-mail to those individuals.

One of the problems with any Web site today, or most Web sites today, is that when you go in, even if you can track an individual who's accessing your site... The Web site is really a nexus, a collection of other links to other places, and the best sites really have the most links in many cases. So somebody goes into your Web site; when they branch off to another Web site, you generally lose them. That's been a real problem in tracking and figuring out what they care about.

With Charlie, what we've been able to do, in essence, is that rather than branching out of our Web sites when they go and access other information, it literally brings in those external HTML pages so you don't lose that individual. It actually draws them into your site so you can't lose that tracking capability. In that way it helps you learn about a user's Web habits and their information requirements, which is very important in enhancing our database of information about each individual user. It also enables us to maintain connections with each user for longer periods of time.

Finally, perhaps the most exciting capability of Charlie is that it actually is robust enough to create HTML pages on the fly in real-time, based on these user profiles. So back to my car analogy; if you're an individual who likes sporty red cars that are convertibles and your wife happens to like boxy town cars with the rich Corinthian leather, when they go once into any given automotive site that we've developed we know what they like. You don't go into the Pontiac Home Page, you go into that individual's Home Pages that happens to be sponsored by Pontiac.

So the guy who likes a sporty red car, he sees the file with the sporty red car. He sees the power options on that first menu that comes up, whereas his spouse will see an elegant town car and all the information that she needs to know and wants to know about the interior, the sound system, the accouterments of the car. Again, [that's] living up to the promise of interactivity, making it truly personalized. The more relevant it is, the further up the sales curve you are and the faster you're going to sell your products.

The last thing it does [is that] it allows you to speed navigation to the site. One of the problems has been access time with a Web site, so if you can go directly to the information about a consumer you don't have to sit there wading through page after page that you don't give a damn about. You want to get right to the meat of the matter, and this is something Charlie provides.

In closing, I just want to give you a sense of what it looks like very quickly. You would go in here, enter your password and your name. You would then go in and be able to choose which constituency group you are, if you're an academic, an industry allied association member, a media person, what have you. If you're an academic, you'd come in here. You then would be able to select what kind of teacher you are: a graduate school teacher, high school, what have you. Then you'd be able to go in and look at the information that is relevant to you.

You do that once; the next time you come in you go right to this section and you go right to the area you care about. You can always go back to that Home Page and look at other areas for the media, for the government, for other constituencies if you wish; you're not forced to stay here. But the idea is to make it as personalized as possible. There's sort of a mall there.

Anyway, in closing, this is the multimedia pyramid. We talked a little bit about the on-line universe today; I'd just like to add one final thing before I get off and that is, in essence, that whenever you develop content for your clients or for yourselves, whether it's on-line for the commercial on-line services or on the Web, make sure that you design your content in such a way that you can leverage it across the multimedia pyramid. So those building blocks are really applicable; this provides you with real cost savings and uniformity when you develop all of your content, and makes sure that you get the message across effectively for your clients.

Thanks very much.

Andrew Jaffe: That was a good warm up. At the end we'll have [inaudible], or after the presentation or at the very end of our presentation for you to try and get on the Internet and show us one or two of these sites.

Leslie Laredo is Director of Advertising Sales & Development for AT&T New Media Services here in Cambridge. This was a company that was originally Ziff Davis Interactive, where she performed similar functions before it was bought by AT&T in December of 1994. Before that she spent six years at Prodigy, and before that she was one of those pioneers in Videotext, which I assume is only about ten years ago, but sounds like when I was little. I remember myself when Videotext came along, and Knight-Ridder lost seventy million dollars in it. At any rate, here we are in the present getting ready for the future. Leslie, tell us something about AT&T's new video services and how you view the Web.

Leslie Laredo: Thanks. Actually, I sold my first Videotext ad in 1981 and sometimes I get introduced as the oldest living interactive ad sales rep. Thank you for not saying that.

Andrew had asked me to give a little perspective of the world as I see it — since I've been around way too long and wish I was old enough to retire, but I'm not — and then I'll go on to show the new service that AT&T New Media Services is launching. In fact, it's available effective today, so we're very excited about that. I'll actually do a live demo, since the phones seem to be working.

Just a short perspective on the last twelve months. A year ago I was going around with presentations at various forums; I think I did Internet World last year also, and I thought things were pretty fast and furious. In the last twelve months it's been like warp speed, and I say this and a lot of people nod usually and say, "God, it's the same thing for me." I've had four jobs, two companies, four different divisions and four sets of business cards in the last twelve months. It's been pretty amazing.

I went through working for Ziff-Davis Interactive and got with AT&T — [which] changed from Interchange, owned by Network Company New Media Services — and then recently we got split into three companies. Every time I get a new business card I'm sure we're going to get a reorganization. It's been fascinating in that perspective, but it's also been just this warp-speed view of the world. When I talk about my job now I say, "God it's great, it's cool, it's thrilling," then it's scary, it's daunting because there's so much change and it's hard to keep up on it.

We get some news services fed into our server to get news bites. In the last six months there's probably thousands and thousands of articles just on our business in there, and to read them all every day is impossible. The worst part is that I'll say something today, and I hate being recorded now because what I say today sounds stupid tomorrow. I gave an interview for Jupiter in one of their magazines or their newspapers a few months ago; I was interviewed in June and it appeared in August and I read this interview that I had given and I went, "God, I sound so dumb." It doesn't make sense any more. It's very frustrating. So now I ask everybody to say exactly when they took the interview, because that counts a lot.

But the most interesting things for me... A year ago I was sort of dismissing the Web as sort of marginally important. I've changed my mind dramatically. It is the most staggering event; I call it the "mega-event." It's now not only merged, but it's accepted as a form of marketing communication for most large and small companies. It's been driven by the rapid advancement of a technology that I'm sure all of you are deeply involved in: the impressive growth rates that are going on in the on-line services.

A year ago there were about five million on-line subscriptions to commercial services. The last I heard was eight million, possibly 9.2 million by the end of this year. That's just

amazing to me. I was around when there were tens of thousands, and it's just [getting] exhaustive coverage; every day in every major trade, every major general consumer magazine and newspaper there's coverage of our industry. My mother started a little clipping service, and she sends me things that she finds in her neck of the woods.

Then [there are the] deals and deals and more deals and, of course, all the hype. Every company in this thing in a big way loves to generate PR, whether it means something or not. So I thought I would go through a list of things that have happened just because I think it gives some sense of how hard it is to stay on top and make really important decisions when everything changes. Personally, starting a year ago, Ziff got sold to AT&T and Ziff got sold again, or is in the process of being sold again.

AT&T bought Interchange. Microsoft announced its plan to acquire into it and, of course, that didn't go through. MCI invested two million dollars in the News Corp. Delphi Service. IBM announced it's buying Lotus, and Disney and Cap Cities plan to merge. Time Warner and Turner Network are merging, and AT&T announced that it's moving up. There's probably a few more other mega-ones in there; I just didn't get to all of them, but if you think about one industry in that length of time — all of these things have huge impacts on us and these mergers will, as the year goes by, start to become something as products and services come out of them. I actually thought about giving five or six lists like this, but I thought that would get kind of boring and I don't like being boring any more. I've been doing this too long, so I decided to do it the Jeopardy way.

I actually got on the Web last night. I was trying to download the theme song for Jeopardy, and the only thing on the Web was Alex Trebek talking so I couldn't get the theme song. I'm sorry. This is sort of a flat presentation, but please answer your answers in the form of a question.

The first question is: who in June of 1995 inaugurated the first WorldWide Web server giving the public access to the Federal Government? Answers? The answer is, "Who's Newt Gingrich?" No one got that one? All right, let's try another one.

How about, "he holds the first Senate Internet Porn Hearings." And the question is, "Who is Exon."

You have to keep on it. This is very important to us, but he was way ahead of Senator Exon in addressing porn in the Senate — you had the answer — "Who was Bob Packwood?" That's not an industry one, but okay.

The government agency that Steve Pace hates. "What is the Justice Department?"

The event in August of this year that turned tens of thousands of AT&T managers into lobbyists? "What is the 'T Nations' Bill?" All right, very good.

The on-line service that introduced the first Web browser. All right, good, all right, I should have put up dollar signs, that would have got you going. I'm not competitive.

The new on-line services that gets members to pay for beta when it's mostly under construction — I want [Steve Goldberg] to answer that question. Thanks, Steve, I told you I'd get you one.

There's someone here from Microsoft — I told you I'd get you on one of these. I like this one. "The on-line service that provides every adult in the free world with ten free discs a month."

"He was rumored to be buying the Vatican this year."

"This company's rumored to be buying Sears' stake in Prodigy." You know who that is? You didn't hear that rumor? That was CompuServe. You've got to read these news bytes more.

The last question here, worth \$100. "What's the company that launched the first comprehensive business-to-business on-line service?" Andrew gets \$100.

That's just an idea of all that's going on; I mean, there's just so much, and it all impacts what we're doing. Last year I was actually looking at some presentations I did. We were thrilled at five million subscribers to on-line, this year eight, and as I already reported early on, now it's like nine million.

Last year CompuServe was the largest service; this year AOL has taken the prize. Last year I didn't even talk about the number of commercial Web sites. I knew it was sort of important, but personally I was more concerned about what was going on with the commercial on-line services. This year I'm trying to find the numbers, and the last I saw was 400,000 commercial sites as of January 2, 1995. I don't know what it is now. I don't know if anyone here knows, but it's growing at a rate of 300 a day or something. Amazing.

Last year I knew of no ad agencies with Web sites. This year we can show you dozens and dozens of agencies that are on the Web. These are not just new agencies, and there are ones that have been doing it for a long time, like Jay's agency. It's the O&M, and the major guys. Last year there were no agency of record assignments for interactive; if you're in the media world you know that's an important assignment to get to control the media buying for the agency, the interactive. Again, this year there's been dozens of assignments.

AT&T has given our assignments for AOL and interactive to Modem Media, for example. Last year, minimal research was going on the Web; this past year there's been numerous studies released, mainly from university sites. I saw recently a study of responses. American Internet Study, which is going on right now, just concluded their first wave; it's amazing, because they're now getting some real interesting data in how on-line and the Web are influencing the consumption of traditional media. I think that's a big deal in our business.

So what else is changing? Studies are showing that audiences are becoming mainstream; not mainstream enough for me, but it's not 80-90% male. Some research is showing 60-70% male, which means more women are getting on the Web and getting on-line. [In the] last study I saw that forty million people were on the Internet. I'm really concerned about what's going on in the U.S., and the last study I saw that ten million American have access to the Internet and about 40% of those were through commercial on-line services.

On media consumption, this is the finest number: 54% of on-line households spend less time watching TV, and 16% actually spent less time reading newspapers.

The other thing that's changing is the business model. I know it's changing because Interchange has changed its number in the last year. It's changing, but on the Web you're seeing registration versus no registration. *Hot Wired* registration is required now. *Pathfinder* didn't register, now it does — and you're seeing this going on throughout the industry. The main reason for registration is advertisers want to know who's getting there, and the only way you're going to get it is registration.

But the big thing that is definitely coming out again in advertising is the funding source for what goes on the WorldWide Web, and [the fact] that the on-line services say they need more to keep their costs down and make it more economical for users to spend more time and hours.

The other thing that's changed is access and browsers. A year ago we heard about the access providers to the Internet; now we're hearing the access coming from the commercial on-line services. We're hearing a lot about new browsers, about *HotJava* and *Netscape 2.0*, and this is changing. The funny thing is that people are talking about all these browsers coming down; well, it's still this issue of commonality and oneness where if I have the *Netscape 1.0* and I don't happen to get the new one, I'm not going to read it and see sites that are created. I don't know if everybody's thinking about that, but it is going to impact how the world is going to view what you're doing on the Web.

So what does it mean to me personally? Well, if I'm speaking of the advertising media buying creative sales organizations out there, your clients are demanding that you participate. They want you to justify the results. Now, that's hard to do because of the problems with measurements. Agencies are having a hard time finding and hiring, training, and staffing the people they need to create, plan and manage all of these interactive projects. And I know, because I get calls all the time from headhunters who ask me if I know anybody. My Rolodex is great, but it's not that good. There are no standard tools and measurements. There are no less than nine — and now Charlie makes ten and counting — different auditing products out there.

There are probably a lot more than I know about, everything from I-Pro — which is becoming sort of the standard — to WebTrack to Digital Planet. There's a whole bunch out there that are all trying to become the standard in how media gets measured and reported on. Probably the worse part is that we're all being forced to make decisions so rapidly with very little data; I'm being asked to come up with rate cards and pricing and all sorts of things. For what we're doing we don't have usage data yet, but we've got to make these decisions because the world is changing around us and we can't sit around and wait for the data to come in.

So, the implications are huge for advertising, especially on the Web. There are different pricing scenarios, and it is really tough for agencies to decide how they're going to buy your site versus another site, [whether to] put a banner or button somewhere or be involved in more in-depth content. You're seeing that Prodigy, I think, is still doing CPM; maybe not. I haven't been there in a while, so I'm not quite sure what they're doing.

You see guaranteed impressions on a lot of WorldWide Web sites. They're saying "We'll promise X thousands or millions of impressions in a certain time period." I heard this is no longer going on, but Individual, Inc. started this auction: you decide what your Web play, or what the link is worth, and then you pay for it. The highest bidder pays the second highest price. When I heard that, I kind of laughed and said, "Gee, if they don't know what their site is worth, who else does?" How could we know?

[There are] lots of sales commission deals. You go into the Internet Mall branch on some of the stores on Prodigy, CompuServe, and I'm sure they are all paying based on percentage of sales. And a lot of what's going on now I call "merchandise positions."

A lot of Web sites are major publishing sites that are coming out of the major print in broadcast companies who are just packaging it all together. "Buy an extra spot, we'll throw in an interactive. Buy an extra page and we'll throw in our interactive." I personally think that's really bad, and I applaud one of the few companies that I know is not doing that — CMP, which is selling off the rate card and not merchandising, and packaging interactive with the rest for media products. I think the only way it's going to stand on its own and have its own value is to not have its own rate card packaged in.

Back to the audience issues. I can't stress this enough; it's exciting to hear what Jay's doing with his Charlie database. But there's also the issues about collecting data and privacy and how it's used. A lot of people are using data, and I heard of an ad — I think it was *Penthouse* that was doing some kind of promotion about why you should put an ad in *Penthouse* versus *Playboy*, because they had more hits. They're only interested in the number of hits. You've heard the discussion; is it a hit? Is it a visit, is it a session, is it the same user? How do we know which one? How do we compare? There's nothing standard across almost any site.

I could put a spreadsheet up here and show you what the top sites are doing. Every single one is different; there isn't one set of commonalities amongst them. There's no category of standards, whether it's all Internet-sized or whether it's all commercial on-line services. There's nothing standard, so it's a daunting exercise for media people to say, "Where should we spend our dollars?"

On the other hand, I do think that media buyers and companies are doing this on their own without their agencies. They need to be where the “cybermasses” are, and they need to be on the hot Web sites. They need to be on the commercial on-line service, because that’s where the people are if they want to get noticed. Jay made that point earlier.

You have a great Web site, but what if nobody came? And with 400,000 commercial Web sites there has to be a lot of intense effort to get your site noticed, and that means not just *Yahoo* and *Netscape*; [it means] finding context, finding the right place for your banners and buttons to go and more. Right now the majority of new media budgets are being spent on the creative [aspect].

Million dollar Web sites are being created. I read an article the other day where *Organic* was quoting that their average Web site costs about \$30,000, and now they’re saying their average Web sites are costing hundreds of thousands of dollars to create. Companies are spending more on creative, and not on placement and getting their URL on their packaging, on their ads and in their brochures on other places. That hundred thousand or million dollar investment is basically meaningless.

[I want to talk about] the availability of audited statements. You’ve seen alliances going on; ABC, [Audit] Bureau Circulation is — I think it’s either with I-Pro or WebTrack or Nielsen — is forming a team with the other one, and you’re seeing all these people from the traditional media world trying to form alliances with the new media measurement companies so they can go out there and say that they have something that does this. This still is nothing today.

The great debate, a lot of discussion, [is about] “Should we be on-line. Should we be on the Web? We know on-lines die, commercial on-lines die, just all be on the Web.” I hear this and I hear this, and granted I do have every perspective, but I do think that it’s not “either/or” and it won’t be for a long time. I really think there’s much more power. We think about integrating proprietary on-line service with the WorldWide Web present.

Commercial on-line services give you market access. In the case of AT&T, we have ninety million customers to whom we can market. That’s terrific market access. You don’t have that with Web sites. They said we’ll have market access if they can get their product working better with their Windows 95 product out there. On-line services can offer much more defined audiences.

Prodigy has great media. They’ve really spent a lot of time defining their audiences by doing audience studies, because they know who is signing up across the commercial services. On-line services tend to do a much better job tracking and providing research on who’s there. Some on-line services do better, some do worse, in terms of presentation and tools. I won’t argue that the tools from the commercial services are great, but I would argue to take a look at the AT&T Interchange tools because they think they’re better than all of them.

You can promote extensively on the Web and commercial services. I think you need to think about that in both places all the time. I was personally involved with some accounts when I was at Prodigy that did some heavy duty promotions of their Prodigy sites on Prodigy. Coors did a promotion in the NFL area and had terrific response; some of the car companies did too. So I think that promotion works if it’s done right.

Last of all, context, context, context. This is what’s it all about. You’ve got to be where people are going to want to go. A banner with your logo on it is meaningless to a reader unless you’re branding something to them in the areas that they’re in. If I’m reading a printer review section in one of the PC computing services, I’m more likely to hit on that versus if I hit a different kind of art. I think looking for context for your product and your company is incredibly important.

There’s a lot to get done, and sometimes I think, “God how are we going to get this done?” Every time I think they can’t be done I think, “Well, here’s some quotes, you know.” I

like going back not that many years when someone from IBM was saying, “What good is a microchip? Who would want a computer in their home?”

In 1977, I was in college and Bill Gates was saying that 640 ought to be enough. And my favorite one actually is this one, which is, “Who the hell wants to hear an actress talk?” I sometimes open my presentations with a little blip from the *Singing in the Rain* video. There’s a little segment in there which actually showed the first time a talky movie is on and people in the audience are accusing the producer of having actors behind the screen who are really doing the talking.

Now for the commercial that I’ve been allowed to do, a quick commercial. AT&T Business Network is commercially available today and you can get over to the World Trade Center or wherever it is, where it’s a mess. Go over there and check our booth. I won’t say anything bad about Meckler because, as I said earlier, “How can they mess up?” It’s such a great conference and they can’t get people registered in the door. Wasn’t it at Internet World in San Francisco six months ago where people were waiting two and a half hours in line to get in? Anyway, they’ll get better. It’s a good show.

AT&T Business Network is an indispensable resource for managers and professionals who need up-to-the-minute news, business and financial news, for activity software packaged in toolkits to help them do their jobs better, for depth references and research databases. It does also offer a communications network so professionals can talk to others in their industry and in their profession.

We are totally integrated with the Internet. The most important thing is that it is an Internet-based publishing platform. We are the only service that built-in the TCP/IP protocols, which gives us seamless integration to the Web, and I’ll show you that. You can access Interchange from the Web, so you can dial in through phone or dial or access through the Internet.

I’ll give you a demo real quick because it’s going to be hard to see over the content providers. We have about [inaudible] signed content providers, and that number’s growing every week. Probably the most important on the list is CNN. We just cut this deal; it’s a multi-year, multimillion dollar deal. We’re seen as a major news source to the AT&T Business Network and we’re also getting about sixty spots a day on CNN, beginning in about two weeks, for them to promote. So every time there’s a news item, get more on CNN News on-line and go to AT&T — there’s a business network. So that’s very exciting for us. Here’s some more featured brands.

These are some of the ones that are up there now. I’m going to get right on-line; I am still connected. We’re at Interchange on-line. 14.4 access. I’m going to tell you this so you see how fast it’s moving. This is the Interchange Central News Service. It’s a news, business, sports, weather — we created an area where if you’re on-line for business information or some of these other targeted vertical publishing areas you wouldn’t have to sign off and go somewhere else if you wanted to find out who won the World Series.

I’m going to download a highlight screen. We do multi-task, and since that takes a little bit of time to download, I’m actually going to go back to it and I’ll pop up to News. Here’s the news section, and you’ve seen it come down. Now I’ll go back to sports, and here it is on-line. So in background mode we were seeing some stuff come down the line where you’re seeing some foreground.

M: What is this site called?

Leslie Laredo: This is not a site, this is a proprietary on-line service developed originally by Ziff-Davis Interactive and now owned by AT&T in the New Media Services Group. It's different. We have different publishers on-line.

Ziff-Davis has whole publishing areas on Interchange. The *Washington Post* does, too, and what's good about these businesses for these companies is that they can actually manage not only their own info space, but they also own their customers. They do the marketing, circulation, retention of their customers and they also sell their advertising. Here's the Business Network.

I'm being given a time watch here. Here's the News section, and we have featured brands down the left and then editors pulling out areas on the right. I want to just point out that AT&T does not create any news; We are actually an aggregator and our editors are really information managers.

Here's the automotive, and I'm going to go into News on how we integrate the Web. Now, you don't see a lot of Web globes right up front because we're still dealing with our users using old versions of software. We just released our new version of software that has a *Netscape Navigator* to 1.2, and that's why some of these are a little bit hidden at this point until we get everybody upgraded on the new list of software.

So I clicked on the globe. Depending on who the site is with, we'll see how fast it comes up. It looks like it's pretty fast. There, you've seen 14.4 access to this site on the Web, and this is Ergo Web. I've not been here before, so I'm not sure how long it will take, but you've seen the seamless integration of *Netscape Navigator*. Not too bad at 14.4, and you can go back and forth.

We're having editors integrate Web content into the Interchange content. Are you really going to kick me off the stage now, Andrew? All right.

Andrew Jaffe: The commercial that took too long.

Leslie Laredo: I'll be around afterward if you have a questions. You can go by the AT&T booth at the Exhibit Hall and see the demo of the service working. Thank you.

Andrew Jaffe: That was great, Leslie. Next time I want to play Jeopardy, I want to know your world view and I want to see you supplied with the Web more. I think you could have had more on the Web and your view of it. That was a wonderful overview and really a lot of data.

While she's getting unhooked and Andrew Nibley is coming up here, I'd like to call attention to *Internet World Magazine*. The November issue has an article on the Internet's phenomenal growth mirrored in startling statistics. I don't know whether these statistics are worth much, but we're coming to feel that in the U.S. there are about thirty million people with access to the Web, about three million of those are in households that are connected. Most of them are connected from their workplace, so it's hard to know at their workplace how many people are actually using the Web. Yes?

M: [Inaudible] e-mail access versus real access to the WorldWide Web?

Andrew Jaffe: A good point. I'll let you read the article and judge the statistics here for yourself. I'm not going to get into them, but obviously a lot of that is e-mail, and either your company is claiming that it's on the Web but you can't get into the Web at your desktop, or your hooked up to an on-line service but you can't really download the browser and you're being counted. So there's a lot of space in the numbers.

I think what is interesting, and we'll get back to it in our question period, is the whole question of what are we counting? Are we just counting hits, are we counting your access or are we counting your actual involvement?

With that little transition... You're going to work from your seat there? Good. Andrew Nibley, like myself, is a real editor, a real journalist not trained in the art of business. He's learning it sort of seat of the pants. He's Editor and Executive President of Reuters New Media, which was formed two years ago to create new products for the consumer and corporate markets. They have now a suite of business information products, a suite of on-line products, an Internet news product, and a suite of products now they're developing just for the advertising industry which includes Ad Value, a transactional system and Aim 20 for creative end, and they're planning even more products just for the advertising industry.

Andrew was editor for North American Latin America, for news and television, and before that he was Reuters' news editor for Europe. He's had fifteen years at Reuters, and he's now having a lot of fun exploring this new way of communication. Andrew, I'd like your view as somebody who is actually creating content and trying to decide how to deliver it to users.

Andrew Nibley: Good morning. Normally, when I see a crowd this size I have an overwhelming urge to break into a rendition of "Feelings," but my four-year old has given me the plague today so I'm loaded up with various drugs. I would appreciate it if you would attribute my remarks to me and not to my poor company and employees there.

Andrew was kind enough to tell you what my official title is. This is actually what I'm known as in the shop, largely because the people who work for me are half my age and twice as bright as far as I can tell. As Andrew said, I'm going to give you the perspective from the content provider's point of view. The same four-year old who gave me the plague this weekend strolled up to my bed as I was waking up from my third trip to London in a week and a half, and as only four year-olds can he got one inch from my nose and he said, "Dad?" I said, "Yes, son?" And he said, "For the first time in my life, things are finally going right." I feel the same way, son.

It's a good time to be a content provider. Frankly, I don't care whether the commercial on-lines win. I think they're both going to win, actually; they both need content, so that makes it a pretty good place to be right now.

A little bit about Reuters. Reuters has been a content provider for 150 years, and I think it makes it the oldest news agency in the world. We've actually been in the on-line business for the past 40 years, primarily in the foreign exchange industry.

When I joined Reuters I think we made about four million a year. We're now a five billion dollar company, so the short answer is, "Yes, you can make money in the on-line business." We paint with all the colors in the multimedia rainbow. We own the world's largest television news agency; we have 138 bureaus around the world, which is more than anybody else; we have relationships with over 200 exchanges so we have financial news and data; and we also have global photo operation and a global graphics and audio operation.

When we formed New Media two years ago, we weren't exactly sure what new media was. Interactive television seemed terribly popular at the time, but after one year in the business we broke it down primarily into main business groups: business information, on-line publishing and corporate television. The yellow groups are the ones that are 100% controlled by Reuters, and the white groups advertise education and entertainment.

We have business ventures there with other partners. In advertising we have 50% ownership in a company called Ad Value with Group W. We have education venture with TCI and an entertainment venture with [Riddell]. Andrew mentioned that we have some product offering primarily for advertisers; Ad Value is a transactional system that allows you to buy and sell national spot television time. It's a transparent system that allows the ad agencies, the reps

and the television stations to see the process all the way from start until the commercial is actually aired. Aim 21 is a creative service that allows corporations to keep track of all of the ad work that they've done.

If Coca Cola, for example, has done an ad campaign in the States, it allows the branch operation in Taiwan, for example, to have access to it on the computers, and they can "re-jig" it in a digital format and make it appropriate for that market.

Next month we're launching a product called "Ad Briefing" which has *Advertising Age* in it, among other publications, and a real-time advertising news service done by Reuters' Editorial. The real-time service will fit over a database of some 2,000 global publications, a very easy point-and-click research tool for the advertising industry.

These are our major on-line clients now. I forgive Leslie for not mentioning Reuters' in her presentation, although she did have her cursor over it. I'm sure you all picked up on that. In any event you'll see we pretty much have relationships with all the major players.

We've been in the on-line news business for a good seven years, so we have a jump on some of the other content providers. I think it's important to note that a lot of publishers have simply taken their existing content and slapped it into an on-line environment and it hasn't worked terribly well.

I think one of the things that a news agency like Reuters brings to the table is that it's real-time information. It's not the same, it's changing all the time. I read the *New York Times* this morning, but I don't particularly want to see it on the computer screen. What we bring to the table is that the information is constantly changing. It's different information than you can get any place else.

Here are our major Internet clients for the time being. As I said before, I think these two groups are gonna merge in the future. In the commercial on-line arena, we get some of our revenue from subscriptions and most of our revenues from royalties — when new users come on to a service we get a percentage of that. In the Internet environment it's almost 100% advertising.

Why do people go on-line? Basically there aren't any surprises here. I think the number one reason is exploring. This presents a real challenge to the 400,000 commercial sites out there. Why would anybody go back twice? I don't know how many of you are surfers; when I go on-line, I look at a site once, and I may go back to it in six months. Primarily, I'm exploring and I'm entertaining myself. I'm looking to see what somebody's done, what's cool, what's not cool. So you have to find a compelling reason for people to come back.

Communicating is probably — if there is a killer app now that's probably the largest one. People are using the Internet and the on-line services to talk to each other; they're looking for information. And transacting is starting to come on. It isn't very well developed yet, but I think that it will play a much larger part going forward. And there's the entertainment value: fun and games.

The good news is that people think they need to go on-line. In the fourth quarter of last year, for the first time ever, more Americans bought personal computers than television sets. Most of those personal computers had modems. In December last year — I think this is an interesting one — for the first time ever, Americans who had both a color television set and multimedia PC spent more time on the computer than they did watching television. If you go into the age groups in the study, you find that with teenagers and kids in college the percentage is about 70/30 for preferring to spend time on a PC than watching television.

The growth of the on-line market is up for debate. This is our best guess: we think there are about 7,300,000 today. There are other studies that show 8.5 or 9.2 [million], but we've tried to factor out multiple users where somebody is subscribing to both AOL and Prodigy or

CompuServe and Prodigy or a number of services. In any event, the trend is that in the next two years we think that it will double.

Here's some more good news: a recent study by Mecklermedia showed that 81% said news was the thing that they'd be most interested in seeing on the WorldWide Web; 75% wanted computer related information — which shows that cyberspace is still pretty much of a techie crowd, but as Leslie said, that's changing; 68% wanted research and 58% said they wanted to be entertained with movies, games, and jokes.

Here's the bad news. I feel I should say something on that score. Not everybody's sure that they need to stay on-line. A new Times-Mirror survey just out said only 32% of those who go on-line would miss it a lot if they couldn't go on-line anymore, and this compares to 58% of newspaper readers and 54% of cable television viewers. So we still need to find the killer application out there to make sure that people want to stay on-line. This is a quote out of the survey. "A few see on-line activities as essential to them, and no single on-line feature with the exception of e-mail is used with any regularity."

The question was, "How many on-line services does Times-Mirror have?" They have one, I think. In the Mecklermedia survey, only 3.3% said they definitely would be willing to pay for information. There's still 52% out there who haven't made up their mind and say they might. Around 14% said if you gave them a free sample and they saw that it was information they wanted they would be willing to pay for it. About 30% said absolutely not, never, don't want to be bothered.

We took our first plunge into the advertising revenue sort of things with yahoo.com, which is generally considered to be the second most popular site on the Internet.

Yahoo is a very good research tool, as everyone knows, for finding your way around the Web, which is one of the problems. We talked to them about providing a real-time news component that would give them another dimension to bring even more people to Yahoo, and we're very happy with the relationship. We derive our financial nourishment from the advertising that they sell, although the relationship's only several months old and I wouldn't call the advertising particularly dynamic. It's one-dimensional, it's linear at this point. They're actually selling more ads at higher prices than either of us imagined were possible at the time.

I think as Java and HotJava and VRML and some of the programming languages become more popular and the content providers and the ad agencies start writing in those languages, I think this is going to be a very lucrative market, indeed.

Leslie said there's 400,000 commercial sites. Our count is that there are 13,000 corporations now. Those figures aren't incompatible; most sites have a number of pages in them, lots and lots of pages. A lot of things that are commercial sites are sort of a one-man band at this point, and we're counting the big corporations that have taken up sites on the Web. That's a pretty significant amount. In the United States, for reporting purposes we follow 9,000 corporations. So if you think there are 13,000 globally on the Web, that means almost all of the major corporations now have a Web presence.

What we're designing is something called "The News Machine" to fill the needs of these corporate Web sites. The problem that they have now is that the corporations use their Web sites primarily for sales and marketing. They slap their content up there, make their sales pitch, and as I said before most people are surfing the Net and they never come back.

So how do you get the people to stay at home down on the farm? They need to have some kind of unique content to make somebody want to go back there day after day after day, and what we're coming up with is a concept called the "News Machine," which will allow designer news services for each site. In that way if [Smith Kline Beecham], for example, could come to us and say "We want a pharmaceutical newswire," that goes FTP out to the site every day.

Ford could come to and want an automotive newswire, [giving them] tailored service. The concept is that we have all these big pipes of content and we can slice them and dice them anyway you want to using our coding system so that you can come up and fashion your own news service. Since it's real-time, that means it will have new content all the time. There will be a compelling reason to go back to the site the next day.

Our conclusions are that there are essentially two different markets. There's a consumer market and there's the corporate market, and we need to serve both. As I said before, in the consumer market we now think that we will generate almost all of our revenue from advertising. As the commercial on-line services become sort of mega-Web sites, we'll get less and less money from subscriptions and royalties and much more of our income will be generated by advertising. This won't be the case, we don't think, initially in the corporate market or in the business information market where people want information to make more money and they're not terribly interested in being pitched.

We think that the revenues will continue to come from subscriptions and royalties, but increasingly down the road the transactions themselves will be the most important source of revenue from our point of view. And that's it for me.

Andrew Jaffe: Thank you for being brief, Andrew, and getting right to the point. Some interesting points. Now we can get into some questions.

Let me ask a couple of questions just to warm up the panel and get in a different mode here. You can get those microphones so that Leslie can access one of them, Jim. There we go.

Just a quick run from the panel, and I just want a gut answer. [Is this statement] myth or fact? "Advertisers are ahead of publishers in creating interesting Web sites that have content you'd want to come back to."

Jay Sandom: Myth.

Andrew Jaffe: OK, What do you mean? Just briefly.

Andrew Nibley: You think that advertisers, that publishers are doing well? Yes, I think that by and large most of the publishers actually have done a better job in leveraging their assets than advertisers have.

Leslie Laredo: I don't think that advertisers realize that they are publishers on the Web. There's a few sites that are really good. The Zima site does something different. Toyota has a new site out that's pretty different. It has more content, but I think for most part the agencies now realize that, indeed, they are publishers, and that's the problem.

Andrew Jaffe: OK, good. Jay, why don't you move over just a little bit? The two of you can get comfortable sharing that microphone. Andrew, you get one to yourself down there at the end. Myth or fact? Andrew, give your viewpoint.

Andrew Nibley: Right. I tend to agree with the comments just made by Leslie, who I've been calling Lori for the last half hour.

Leslie Laredo: I tried to kick him under the table.

Andrew Nibley: It's those drugs, it's those drugs — and she's now allowed to call us "Rooters." That was a big problem when I used to interview, when I used to go to the White House. I used to say, "I'm here to interview the president, not fix the plumbing."

I think it's a mess. I think that for the content provider, it's easier to make the transition. I agree very much with the point Leslie just made that advertising agencies have to start seeing themselves as publishers. I think it will get a lot more interesting when they can do some of the three dimensional things that the new programming languages are going to do, and then I think they'll probably leap-frog the publishers.

Andrew Jaffe: OK panel, I totally disagree with all three of you. I think advertisers are well ahead of publishers. I think publishers are still trying to figure out what to do besides put their content out there, and advertisers like Ragu or Zima are getting it on how to involve people.

Up to now the true at-large advertising agencies, general service agencies that we know of, are not creating these sites; they're mostly either being created by specialty agencies like Einstein Sandom or by the advertisers themselves working with specialty providers. But that's all right, panel. I could be wrong or we could disagree — or I could be right.

Leslie Laredo: Well, you have an interesting constituent there, Andrew.

Andrew Jaffe: No, I don't think... I think I'm beating on ad agencies to catch up. Meanwhile I'm beating on AdWeek to get out there and try and surpass Ad Age. I don't know, but maybe I have a bias.

Myth or fact? "AOL, CompuServe, MSN will either be Internet browsers in five years or be out of business. They'll be known primarily as Internet browsers or they'll be out of the on-line business." Myth or fact? Andrew, why don't you start?

Andrew Nibley: I think they'll definitely be Internet browsers, and as I said, I think they'll be super Web sites. I don't think — well, I think some of the commercial on-line services will be out of business. I think Microsoft Network, AOL and CompuServe will probably be around, I don't know about Prodigy.

Andrew Jaffe: OK, Leslie.

Leslie Laredo: That's a hard one, because I think that the commercial services do offer a point of view. If they beef up security...

They tend to be more "family-friendly." I think the hardest part that we all have, including me, is that we are the inner circle of this. We are not the masses out there. They're going to get on-line next and I think that the hardest thing — because I talked to family members and I don't want to be a focus group one either — but you know, I have fairly computer-literate friends and family out there. Oh, I shouldn't say "friends and family" — sorry, AT&T.

Hey, can I tell a funny joke and answer that question? I actually had my very first meeting at AT&T back about eight months ago, and when I told my five-year old that I was going down to AT&T in New Jersey for a meeting he looked at me and said, "They don't have circles, do they?" So, who said the power of media traditionally is dead? It's not.

I actually think the commercial on-line services do offer a lot. I don't think they'll just be browsers. I think they have points of view and I think that's real important. I don't think I want to go on the Net and have 100,000 places to go to figure what's best and what's not. I think entities out there will provide rating services, provide security, be able to do more customizing;

and focusing is important. If I could tell what would happen in five years I'd be with my crystal ball making a lot more money.

Andrew Jaffe: Okay. Jay?

Jay Sandom: I think that the question is a kind of wrong-headed, because ultimately I think that it doesn't really matter what the delivery channel is, if it's a dedicated on-line system or if it's a Web-based system. I think in the end what matters is the brand identity of the offering, and here we're looking at AOL which has a very defined personality, which, in fact, has been very successful and growing very effectively and very fast.

So whether or not it becomes Web-based or hybrid in the sense of what AT&T is becoming or what the Interchange is becoming — it doesn't matter. The bottom line is, "What's the content and are people willing to pay the money to get into that content?" I think they will all survive if their content is superior.

Andrew Jaffe: OK, panel. Good answers. Myth or fact? "Hits don't count." And if not hits, what does count? Jay?

Jay Sandom: Well, that depends on how you define a hit, I guess. I think that clearly one has to be able to document who's going into his site and what they're doing within a site. The problem with hits in the past has been that if you go into any given Page, there may be a number of discrete elements that make up that Page and that may constitute five, six or seven hits per access. That's really not a hit.

What people consider to be a hit... Is there an individual going in and looking at this particular site? Where are they going? I think they do count, just like they do in mass media. Ultimately, I hate to say this to you, but again I think your question is kind of wrong-headed. It's not about the number of hits anymore, it's about the quality of the relationship that you're generating with that target. That is what this is all about. It's not about the numbers, it's about the quality.

Leslie Laredo: I agree. I think that there's some efforts being done by the Four A's and A&A and the Casey Committee guidelines on that. What's a hit? What's a visit? What's a session? What's a user? I absolutely think what's most important is, who is the user? The more about them the better. Right now there's really no way to do that. So, that's the best of both worlds. I think hits are meaningless, personally.

Andrew Jaffe: Okay. Andrew?

Andrew Nibley: Yes, I don't know that all hits are created equal. I think that a Home Page hit probably isn't worth that much. It could just be somebody surfing around exploring. Drill-down hits are much more exciting because that's the person who's taking the time to get down to a specific piece of information. If they've come through *Yahoo* and they're down in the automotive section, there's somebody who's looking for a car. That's a quality hit.

Andrew Jaffe: Okay, last question. Myth or fact? "E-mail is the killer app." You questioned that, Andrew. You feel we're still waiting for it.

This might be a surprise answer for this crowd. I think e-mail is the killer right now, but I think interactive advertising's going to be the killer in the future. I know in the interactive television trials — I know that's not a deeply popular concept right now, interactive television

— but at that time I remember being in the focus groups where people would say, “I absolutely don’t want advertising, period. Full stop, no advertising. I’m interested in movies. I’m interested in news. I’m interested in sports clips.”

Then we go behind the — I can never remember, two-way or one-way screen, I guess it’s your perspective — we would go behind that and you’d see the fellow play around with the movies, play around with the news and then go back to the BMW ad or whatever and then put it away, and then come back to it and open the door and then go away and then come back to it — and ask how much and how many miles per gallon it got.

The point was, once they saw advertising as not sort of the in-your-face, “drink this beer and you’re going to get the beautiful blonde,” but more as information, something they could control, it became very exciting to them. It goes to Leslie’s point that advertising really is going to become on-line publishing and an information tool.

Andrew Jaffe: Any other comments?

Leslie Laredo: I don’t think e-mail should be in [inaudible] killer app. It is why people go on-line today. I don’t think people will stop going on-line. I think that people will diversify as content gets better and will do more things, but I think right now there’s a need to be on-line to e-mail. I mean, I go on-line every day, every night and I do e-mail off different services, different places. I need to be in communications with people.

I think it’s different from content. Some people would say conversation, chat, e-mail are all a form of content. It is dynamic, organic content that’s being created all the time, and it is the driving force to go on-line. So I think that it is, and that won’t end.

I think that in our world we want to stay more in touch with people of similar interests and like interests who have the same passions and hobbies. I do think it is, and will be — I think what grows up around it will be important. I think, to speak to what’s-your-name, Andrew, Andrew’s point that Reuters, that the more that we can incorporate...

Andrew Jaffe: Arthur, just call him Arthur.

Leslie Laredo: Arthur.

Andrew Jaffe: Okay.

Leslie Laredo: The more we can incorporate that into advertising, into what we design so that the points about being in relationship marketing and communication is part of all of all that. I don’t think it’s the killer application. I think it’s the integration into other things.

Andrew Jaffe: I just hope that was the right question, Jay.

Jay Sandom: Once again, Andrew, I’m afraid to tell you the truth. It makes me a little leery when people constantly strive to search for one particular killer application, because really the key, the key issue in interactivity today, Andrew — he’s going to keep his subscription, it doesn’t matter, go ahead — it’s personalization. We’re not all part of the face of the mass market. We do all have our own individual needs and interests.

So I think that the search for this killer application is really ultimately wrong-headed, because it belies what we are going on-line for, which is to express our individuality.

I think that there are two things, though, that one can point to, and they are very distinct entities. One is this communication, this kind of gathering of like individuals, which I

think is something which we see in chat and conferences, where people strive [to connect] because of how alienated we are in our society today, frankly. We need to go on-line and talk to one another, to people who are very similar to us. That's one major component, part of the killer application that you're seeking.

The other really is a hybrid. I think if anybody looks at compelling Web sites today, coming at it from an advertising agency perspective, it's not advertising. It's really interactive multimedia marketing communications, which means that it's transactional, which means it's information and it's entertainment — it's not one or the other. For any site to be successful it has to combine all of those elements, otherwise people are just not going to come back.

Andrew Jaffe: OK, let's have a quick fifteen, twenty minutes of questions and then we'll break for lunch.

M: This is a question for Leslie. There's a lot of talk about the power that the on-line companies bring in terms of having a community. Do you see any opportunity in offering communities through any Web sites from companies? That community type of feeling?

Leslie Laredo: I don't know if the technology's quite there yet. I don't know the Web. The Web technology means are better, but chat on the Web is not like chat on on-line services, if that's the community you're talking about. I think it's an issue of technology more than anything. I think the on-line services can deliver the community with the services they offer.

M: [inaudible]

Leslie Laredo: I think community is exploding everywhere, and I think people are getting together around content that is important to them. They keep going back to it and can share with people who have like interests. I think if you look at the special interest model, that's really what is happening on the Web and everywhere. It's really about special interests, about people ending up places they want to be because they choose to click on that site — unless they're surfing, which is a big problem. But what they end up doing is going back to it all the time.

In research we've done [we've found] — and not the novice but the experienced Web users — they really only visit half a dozen to a dozen sites. I mean, they'll surf a lot, but they keep going back to those six to twelve sites that they like and are topics of interest to them. They want to talk, communicate. I think the world is sort of segmenting into this, these microcosms of communities around special interest topics.

M: As we start crossing cultural and political boundaries with adverting and the way different people in different countries react, do you see it evolving to where Web page advertising is reacting dynamically to the person or country or place that the hit is coming from?

Leslie Laredo: I think, seeing this — I don't remember the site, but maybe at Levi's or one I just saw recently — you can connect to the U.S. server or to the European server, and you go to the European server and you can get a different site in a different language. So it is happening. I think the big issue in developing a really good site is — a year ago I was cautioning companies, before you go up on the Web, remember you're global, and what makes sense here may not make sense in Tehran or India or Switzerland, and it's a big issue. So I think you see more and more of that.

The more sophisticated companies, especially global companies, are doing it and I think that is important.

Andrew Jaffe: Jay, do you want to add anything?

Jay Sandom: Yes. Actually, one of the reasons why we built Charlie was because we have a lot of multinational clients and they were concerned about not only the language issue but also some of the other issues — use of color, use of design elements that were considered unlucky in the background, for example. How do you deal with those individuals?

Another thing was speed of access, where we found some people coming in at very low speeds and some people coming in — say college kids — coming in at T-1, but a free T-1 line is a college. You know, you want to be able to provide them with the best experience possible, so you need something behind that site in order to really understand how they're coming in, where they're coming in from, at what speed, etc. so you can personalize it and make it relevant to them.

M: We've been dealing with this issue for 150 years because we sell globally, but it's an interesting one. When you're hooking up with a content provider, how global is their content? For most Americans the fellows who tried to blow up the World Trade Center were terrorists. It's a perfectly acceptable way to describe them.

If you're selling into Iraq those people are better known as heroes, as being the only people who had enough guts to take on the great Satan. So as a news organization we have to say, "men who were alleged to have blown up the World Trade Center." I think that as advertisers you're going to be very careful about the content providers you hook up with and how global a view they have.

Andrew Jaffe: In the back?

M: This is for Leslie, to your point of inner circle and outer circle. Does AT&T have any plans to provide direct consumer access to the Internet for the 90,000,000 outer circle people, and if so, can you do it at local telephone rates?

Leslie Laredo: That announcement's being made by WorldNet, AT&T WorldNet, either today or tomorrow so I would look for those announcements. I don't actually have the answer to that; I don't know. We're a new division that AT&T bought and we kind of keep our heads in the sand in Cambridge and get our products done and working.

There's lot's of stuff going on. I think the big point is that AT&T announced a 'global Internet initiative' that involves access, applications, transactions and content. And we're part of the content group and very proud of what we produce. But go to the booth. I know WorldNet is at the booth. Talk to them about their plans.

Andrew Jaffe: Over there, yes.

M: To the moderator's question about hits... You all expressed kind of a dissatisfaction with that measurement and talked about quality. I think Leslie went too far as to say they don't matter. What does, then? What other measurements? There's a lot up on the board. Maybe it's a qualitative measure that you guys have that you're more comfortable with? What other variables that you are using?

Andrew Jaffe: What would you like to see us measure?

[Panel]: When we look at any given access to a site we look we look at the frequency that individual's going into the site. We look at the amount of time they spend within each of the discrete modules and we look at what those modules are against their previous experience in that site. That gives you a very good, very robust kind of perspective on that individual.

You know, we heard about drilling down before. It's one thing to sort of browse across the surface and see the Home Page of a site; it's another thing to really go down and spend some significant time at a given site. We've found that people will spend 7-8 minutes, on the average, with some of the sites that we're developing versus you know, sort of clicking through your 15 second spot on TV here. What are they looking at? How long are they spending with that information and what is their history in that site? It gives you a really clear picture of that consumer and what they want.

[Tape change]

[Panel]: I think advertisers are asking questions of publishers and I know publishers have been asking questions of panelists, including Leslie, with a panel that we did down in Florida about six months ago. Can you tell me, are people really looking at my model, my Page? How long are they there, are they there long enough to get a message? It's the same questions that they're asking in a magazine like *Edward*, but the very fact that they just saw a banner as they were glancing by the Home Page isn't making them feel comfortable yet.

Leslie Laredo: I don't think banners and buttons on tops or bottoms or on scrolling Home Pages is significant. I just think that IBM or whatever, or Lotus, or Sun, or whoever's logo up there is enough to get someone to want to click on it — unless there's some really strong contextual relationship between the brand and the context. Other than that, I'm out there all the time and I'm not getting it.

It's not like intrusive advertising, where there's a great headline, a great graphic, another way to get someone involved in it; and that's why I think that those kinds of hits, I think it's more or less people stubbing their toes across something, opening the door to see what's there and then pop back out. What I'd like to see down the road is, I'd like to be paid for every true customer I deliver to anybody. So you tell me what your cost of customer acquisition is, and I can deliver that customer to you, bona fide that they bought the product and it will cost you a hundred dollars or ten thousand dollars, depending on what your product is, to get that customer. I want to be paid that, because if I can do that and you don't have to go through any mechanism to get that customer, then I want to be paid that. That would be my ideal down-the-road scenario.

It's really about the relationship. It's the lifetime value of the customer, so I can deliver that person to you today, and they're worth \$60.00 today and they're \$100.00 next year and \$1,000.00 the year after that. I want a piece of that, I want a piece of that ongoing, and especially if they're using my forum and my communications to maintain that relationship, whether it's through e-mail or through an updated site or whatever. That ultimately would be the best scenario.

You know, we'll get there yet. Bill Gates said 640 was enough ten years ago, so that's why I put that slide up there. I think we will get there.

M: [inaudible]

Leslie Laredo: About pricing?

M: Yes.

Leslie Laredo: Well, fortunately I'm not selling hits on Web sites so I don't have to make that decision. I can talk to you afterwards on how I do pricing for the Interchange service.

Andrew Jaffe: We'll come right to you after this question in the back.

M: This is for the panel. What do you see happening to the Internet as the more TV-based information superhighway rolls out in a number of years? Do you see that being a function of the Internet, or do you see the Internet becoming a function of that?

Andrew Jaffe: Is interactive television going to threaten the Internet as the Internet becomes even richer than it is today?

[Panel]: I'll take a stab at that. I seem to be talking a lot about convergence today, but I think if you saw the announcement earlier this week about [InterCast], I think that they're going to have to gateway to one another; there will be some video seen on the PC, and I think they'll use a vertical blinking line on televisions to have Web connections. I don't think that they're going to merge the way that commercial on-line services and the Web are and become seamless, the way that AT&T is trying to do; but I think that they're going to have to make reference to each other, and televisions are going to be good at some things, PC's are going to be good at other things, but they're going to have to interact.

Leslie Laredo: I just want to step back and keep talking about the customer relationship and the time that they spend at the Web site, and about the customer support when they're sending e-mail and then the bottom falls out because there's no support behind that. [You need to] talk to these customers where you're starting to build a relationship. They ask very specific questions through e-mail about the Web site about your products, whatever, and a lot of companies are finding they don't have the support there. They're really losing out on opportunities, and people seem to forget about that. They just e-mail. Just drop into a black space.

Jay Sandom: That's a really good point. In fact, that's one of the major weakness we've seen in a lot of companies, in the speed of turnaround in response to those questions. If you're not back to that individual within 48 hours or whatever, then your cyberbrand really starts to suffer. That has been one of the hardest things to talk with clients about, to make sure of that.

In some cases in Australia we were able to hook up with their help desk that was also on their phone system, so they had an existing body of individuals that were already handling that kind of information, who were all PC-equipped, using the PC as a device to access the data that they would then talk about over the phone. So in those cases, if they have a body of individuals in place it really helps. In the case of General Motors and some of the automotive clients we work with, they really don't, unbelievably enough, have a lot of support in some of these areas. And it seems to me that the larger the organization the more like a supertanker they are in turning around and getting just a bunch of guys in there to answer the phone or to answer via the PC. That's been a real problem.

The other one, which I think is also related to this, is the idea of maintenance of the site. A lot of people say, "Yeah, I spend \$300,000 or \$500,000 to build a site," but again, if it's not kept fresh, if they don't understand that we're building a different kind of content... It is like the

publishing business that has to stay fresh all the time to keep people interested; [if they don't] then it's going to fail and you've wasted your money on the outset in developing that content.

So there's similar kinds of issues, and that's where most clients tend to fall down.

Andrew Jaffe: Go ahead, Leslie. We've got time for one or two more questions.

Leslie Laredo: I think you hit on one of the most important issues for this business, the issue of how big companies can change their infrastructure to handle that. One company that I know of, or I understand is doing this, is UPS. They have e-mail open, sending mail to UPS, and they go through great pains to be able to integrate their e-mail to their customer service people so when they're not answering phones they're answering e-mail.

I think that is a trend corporate America is going to take if they're going to embrace the new media and the Web and all the new technologies. That has to change, and it demands a lot; it does demand a PC, it demands a hook-up for your e-mail services to your customer service people, and it's a big challenge. But I think that's the way that it is going to have to go. I think the companies that are real innovative and start addressing the infrastructure issues to deal with new media, and not just make some pretty pictures but get great agencies to do stuff on the front-end but not the back-end, are the ones that will be the real winners. I think that's a great point.

Andrew Jaffe: In the back.

M: Yes, Leslie had mentioned that very relevant ad banners in the vicinity of very relative content seems to make sense for technology advertisers, etc. But with consumer advertising, I wonder if there hasn't been such an effort to keep the advertising unobtrusive, that it's almost not as effective as it could be. Essentially you're saying advertise to me, which is almost foreign to the way we've looked at advertising in TV, radio, even print. How do you see that changing?

Leslie Laredo: I think it's a big creative issue. For example, people have mentioned Ragu; Ragu is being [touted] as sort of one of the better Web sites out there with a commodity-type product in spaghetti sauce on the Web. But they've done something very interesting; they have learned to speak Italian, they do a lot of e-mailing out. I've joined their list, so I get e-mail every few weeks from Ragu reminding me to come back and look at new recipes. And what they're doing, and I think what's real important with commodity-type products, is to have information as part of their brand asset.

The big issue here is, it's spaghetti sauce. Well, not a whole lot, but there's other ways of using information about the brand and related issues about the brand and about the product that can be used as assets to the on-line experience. So I think part of how you get people there is the hot list, what looks cool, and a lot of it is how you integrate your URL and the packaging and the promotion.

Toyota has toyota.com on every ad that they do now. You're seeing it on brochures, and I think that the integration of the on-line with other media has to happen and people go there because they start to depend on it as the place for more information — and this is using information as a brand asset for products that you traditionally think of as having lots of information needs, like toothpaste. Well, there's thousands and thousands of things that you can say about toothpaste, if you're a researcher or something else; you just have to find what's interesting and useful to the rest of the world about it. That's the creative challenge.

Andrew Jaffe: One more question.

M: Yes, back to the global issue. I'm from London. From our perspective, the Net still seems to be a very "U.S.-centric" medium. Can you comment on that?

Andrew Jaffe: Andrew.

Andrew Nibley: Yes, it is. Mostly people going up are U.S.-based, though I will say that the U.K. seems to be next in line. The PC penetration that's coming in the U.K. is coming very rapidly. The commercial on-line services, particularly CompuServe and American Online, are moving in quickly.

What we see is the real possibility out of Asia and Continental Europe for individual services developed in those languages. So I think it's going to be a huge explosion in those markets, and those will all be seamless to the Web in probably the next two to five years.

Andrew Jaffe: Well panel, I want to leave the time for the people to grab a little lunch, and it's a little awkward around here.

I think we've had a good vigorous discussion, with some wrong-headed questions that got started in the right direction.

Andrew, the drugs your five year-old is giving you are good drugs, you made a lot of sense today. Leslie, I've enjoyed being on another panel with you. Jay, I'm going to work on my questions and I hope to be asking you wrong-headed questions again in the future. Thanks a lot.

ADVERTISING FORUM BRANDING IN INTERACTIVE MEDIA

MODERATOR

Andrew Jaffe

Vice President/Executive Editor, *Adweek* Magazines

SPEAKER

David Carlick

Senior Vice President/General Manager, Poppe Tyson

Andrew Jaffe: The magazines have arrived, they're at the back table, the refreshment table, and we've got the New England edition of *AdWeek*. We've got some copies of *Media Week*, and what's interesting to me is that the Museum of Advertising in Portland has organized a traveling exhibit around the image of women over the years and our [Creative VP] has a little view of that and her own views on what's happened to women. There's good and bad; as you know, sexism is not dead yet in some of the agencies and some of the clients.

The other good news is that we're up, this is really the Internet we're showing you, and this is Poppe Tyson, designed by our next speaker, so that's pretty exciting. Our next speaker, David Carlick, tells me that he'll be using mostly slides because he didn't trust me. And David, you were right. It's taken us three or four hours to get it [set] up.

Poppe Tyson is a very well established agency. It goes back 50 years in New York, and it specialized in business-to-business advertising. It's owned by [Bozell], and a couple of years ago it bought an agency in Silicon Valley called Carlick Advertising, which at that time had among its clients Hewlett Packard, Silicon Graphics and some other technology clients. In the last few years [Bozell] has woken up to the fact that this whole thing is going to become important and very rich to its clients, and that it better establish some leadership quick. It designated Poppe Tyson to be the point agency in the [Bozell] family to get this done.

Poppe Tyson established itself a year ago on the Internet. It had examples that it had done for Hewlett Packard, Silicon Graphics, Intel, Netscape and it also designed the Clinton White House site. Today the company has offices in New York, New Jersey, Pittsburgh, Cleveland, Los Angeles, as well as in Mountain View, where David is General Manager. He is about to give up the reins as General Manager of the office so that he can concentrate on electronic marketing communications for the whole company and he will be the head of an electronic team.

David has spoken on a number of panels. Most recently I heard him talk about on-line publishing for the Magazine Publishers of America, and I'm looking forward to this presentation today which really gets down to the basics for us who care about the advertising world, [which we] worry about every day. We have a question, which is: "How do you establish brand equities in interactive advertising? How can you build on the brand equities that are already established for these clients, and how can you translate some of the lessons that we've learned in traditional media to these new interactive platforms?" With that, I'd like to introduce David Carlick.

David Carlick: Thank you. We have a few people from our office here, so I took the liberty of redefining my next job in having Andrew announce it when my company hasn't really given it to me yet, but now we're publicly committed. The real reason I needed more time is because, at the insistence of the people at [Bozell], they say if you're going to understand branding, you have to understand golf, so I've taken up golf this year. I now understand what real advertising is like. I come from Silicon Valley, we don't have real advertising there, and we didn't used to.

This is our site on the Web, and you can visit it at <http://www.poppe.com>. I have brought with me the slightly higher-bandwidth version of this; so, if I can switch the slide projector from the on-line, then I'll be able to make that. I [can] get this all done in my allotted one hour, so I'm going to turn off this box here.

Branding in the electronic media; I'm talking about branding on the Internet as a fairly large topic, and we're going... I was told that I had 2 hours to speak, and then one and then they want to leave some time for questions, so I'm leaving out my first trailer that I had of my baby pictures and my youth and I'll move right into the discussion.

Branding in a digital world, in our opinion and my opinion, certainly [represents] a new class and new ways, so what we've been doing at poppe.com, which is the electronic group at [Bozell], is a worthy experience. When we've made up the program here — oh, I don't know how many months ago — it makes your speech that much more irrelevant because your business plan changes week to week because the market changes from week to week and month to month.

So what we have is — I will call it “news from the digital front,” because it's news from what we have experienced in our work. So, hopefully, in this discussion of branding and advertising in the media I'll be able to help you in avoiding some of the pitfalls that we have stumbled through and help you see, perhaps, better ways to use this area. Then, just because I like to be contrary, I'm going to disagree with every previous speaker and take a different point of view as to what this is and where it fits into advertising.

We did the design and navigation for Netscape, you've seen that. It's an area that has plenty of visibility, so the little “scapes” are there, and our original work shows us that the pointer is better. Now, among all the various myths that the Internet has had, one of them would be that there would be no advertising, and as Leslie Laredo has pointed out, “people are beginning to discover that it's quite the opposite, it'll all be advertising, this is all paid space.” But the definition of what advertising is has changed. Is it advertising here on the Netscape site, a group which we've recently spun off? I tell you, I get a commercial like Leslie — Leslie got a long commercial, she had practically an infomercial.

We have a group called Double Click that is represented here, that represents sites like Netscape. And so like with these ads: when you get to the Visa and MasterCard site, is that advertising? Which part does the agency do, and which part does the client do? Which part belongs to the sales force? The good news for us is that it all has paid revenue for us, but the bad news is for our parent company. It's not bad news, but it's just a very difficult transition to move from a world that's bounded by 8 1/2 by 11 pages or 15 second spots to a world that's unbounded, undefined, as deep as you want to go and as wide as you can travel.

We did the design for the White House and we're working on the new one. And we have tremendous insights into how the government and the political administration see this, and one of the things that you're going to see coming up over the years is that government is going to learn to use this, just as we are learning to use this for our clients in what we're calling “branding” applications.

There's a way to increase the fundamental service that you deliver to your customers and prospects, and lower the costs of doing business — which is a wonderful thing in the case of the government, because this means the citizens can access the services and information the government has to offer without the actual government expense of people to walk them through it.

This poppe.com group is larger and more active in New York than the Silicon Valley group, but it started in Silicon Valley because that's where the people who were going up on the network were. One of the things that we learned in working for companies like Network General is that what people wanted most from the network — and where a company like

Network General comes in — [is to] understand their brand. And you may not think that a company like Network General has a brand — a brand is Levi's, Levi's has a brand, Chrysler has a brand, Network General doesn't have a brand — maybe they do and maybe they don't, but in their little world they do have a brand, they're the sniffer, they're the company that gets the most bugs out of networks.

And the thing that makes their brand interesting and useful to the customer is that these are complex areas and complex decisions for people who don't have very much time. So the way Network General uses the Internet to improve their brand equity is to service their customers and prospects with the information they need to do their job.

Does this relate to a Chrysler? Yes, as I'll show you. The same thing is true with monitors, the same thing is true with Hyundai; but one of the more interesting experiences of a Hyundai, as far as the learning term goes, defines one of the things that changes the whole business of agencies here. We were hired by Hyundai Electronic's MIS group, we are not hired by the marketing people; and this is oftentimes the case of why so many Internet sites are up without the benefit of an agency. The MIS people decided that "this is networks," and networks are taking a very real important and strategic role in the way business works and the way they communicate with customers and prospects. They were going to get something started, so they hired an ad agency.

Then we have the area that we have worked in in helping our parent company to become computer literate, and help their Chrysler stay up-front, which is the Chrysler Technology Center. This speaks to, in a sense, the traditional, and this is a problem that we faced about four months ago. The demographics of the Internet change every two hours, as far as the surveys go, that I can tell. It seems that doing the research on the Internet right now is [like] trying to do a focus group panel during a riot; you're going to get a lot of different opinions all at the same time. "Basically it's growing, and it seems to be mostly males or females, they either use modems or digital lines and they use it either at work or at home." So these are things that we can measure.

The Chrysler Technology Center goes after the idea of traditional branding in the sense that we have an audience on the Internet that is, after all, made up of people who use computers, and people who use computers are in the computer industry and they're interested in technology. So we use this platform or this medium to extend Chrysler's brand as a technology leader, and we show their wind tunnels, and their test areas and environmental freezing rooms and their new vehicles.

When you go to Detroit — I didn't know this, but you don't say "car," you have to talk like a highway patrolmen. You have to say: "Step out of the vehicle, please," which goes against all the things I know about the English language, which is to put everything into one syllable or less.

Then, again, with those collaborating [with us] we worked on the laws of what I believe is the first promotion of a Web site with URLs on broadcast television. The Indianapolis 500 last May promoted the Valvoline site and generated hundreds of thousands of visitors to come in and look at things on the site that had to do with fleshing out the viewer's experience of Valvoline's race team in the Indianapolis race.

So, one of the things that I like to do [is] to disagree with everyone to point out — and this was something that I learned in preparing for the Publishers 2010 conference — that people are constant and technology is not. Technology is really the driver here, or as they say in Silicon Valley, "You can't fight physics." And the physics of all of this are fairly straightforward.

In 1980, when I started out in the personal computing business... Well, actually, I picked 1980 because this publishing conference asked us to predict the world in the year 2010, and so

this is the year 1995 so I just subtracted 15 years using linear mathematics and said, “Well, let’s look at 1980 and see where we were then, and predict the year 2010.” And that isn’t so far off when you consider that the microprocessor has been invented and Moore’s Law has been in action.

And Moore’s Law is the law that predicts that the density of devices on a semiconductor will double every 16 months. That’s actually been fairly true of networking and screen display, in real dollars — not adjusted for inflation in 1980, when I first started selling personal computers. We’re so actively involved in the Internet because we were around at the launch of the personal computing business and saw how it can go from something that has so much potential to something that starts its commercial success quickly, and we decided that this area was going to do that.

In about 1980, a \$3,000 computer had 60K or 64K for memory, and this is a deluxe model. Most people bought it with much less. If you had a dial-up modem [it was a] 300bps modem, and if you had a direct connection of any kind, a digital line, chances are it was a 56 kilobyte line, and the average person in our industry or in our world spent zero hours a day on the PC.

In 1995, today, if you go to the computer papers and look in there you’ll find that the screen pixels are on the average of 786,000 and that more and more systems are showing up with over a million. [You’ll find] that the average memory is 16 megabytes and the dial-up speed is 28,800 bits per second, and the direct connection, more often than not, is 1.5 million. And then, just using the simple laws of gravity, you project that in 10 years you will have X number of millions of pixels available in some form or another, and we’re all be lugging around 600 pound cathode-ray tubes that can show home movies and we’ll have them strapped to our wrist and it’ll be the first PDA that really works.

There’ll be on the order of four gigabits of memory — and you think there won’t be, but if you read [George Gilder] you’ll see that he has proven that the only rich software people are the people who use too much memory. Dial-up speed will be on the average of today’s digital speed, which is 2.6 megabytes, or whatever, and the direct connections will be 36 and the kind of speeds that are now being given out by the network industry.

What that all basically means is that in 1980 that computer, that little \$3,000 thing there, gave Morse Code to an industry that by 1983 was being named by *Time* magazine as Man of the Year. I don’t know how they thought of the computer as a man, but they named it the Man of the Year. It should have been the Person of the Year; but then we have a writer up in San Francisco, Herb Caen, who thinks that to be politically correct you no longer have your mailman, you have it delivered by a mailperson.

In 1995 we have another of these flashpoints. 1980 had the flashpoint of the microprocessor and standardized operating system; in 1995, more or less, we have the same thing, when all this computer horsepower arrived and, of course, the digital Internet arrived. And the digital Internet did the same thing for the Internet business that the explosion of the microprocessor and standard operating system did back in 1980, which is that it just created this change. We had personal computers in a sense; Digital Computer Corporation made their one-user system, but until DOS and Apple standardized things where people can write standardized applications and run them on standard microprocessors with more or less open industry standards that everybody can make cheap and people can have happen, it didn’t turn into a landslide.

As soon as there are open standard issues that turn into a landslide — we have had network and dialup networks and all kinds of proprietary networks follow the same period of time — but until there was a standard by which anybody can have a file, read by anywhere in the world, by any computer, by any microprocessor under any software, we didn’t have that

explosion. But when that standard emerged the explosion emerged, and you all know the story of going from three to 50 to 50,000 to 120,000 of registered commercial users and all the things that go with that standard.

So we have to prepare ourselves and our agencies and clients for moving into that world, and what that world basically is is the worst in the universe, one that we're calling "disintermediation."

Now, the Clinton Administration is very delighted with the concept of disintermediation. They think, and rightfully so, that if you can go to the Internet Web site and get the Administration's position on the issues that face the voters, it would be a lot like what happened during the last election when people got up and had a citizen's town hall and asked questions about things like "Will there be jobs," and "What are you going to do in foreign countries?" as opposed to things like "Were you really out with Fawn Hall, and were you having an affair?"

And at the same time we are facing, in the media world, a disintermediation of a whole new class of information brokers that stand between our customers and us, as advertisers and sellers. Oftentimes that information broker is someone that wears a headpiece, that sits on telephone and answers 800 numbers, and a lot of what companies have been doing in terms of building is trying to reach people at various levels and trying the process. I'll go into that as we go along.

The basic deal that we see happening here — and I'll give all the examples — is that this is not a medium; in a sense, it's a computer platform, and it's giving people a shortcut around what were the traditional media interpolators and [giving them] a new way to look at things. That is the good news and the bad news.

So, in taking this as an open network publishing model, we've put up price for basically every car company that has a site. *Batman Forever* is there, and you can see a promotion for all the paid entertainment. *Mercury News* is there. Knight-Ridder just bought a giant server for every newspaper in their network, and the newspapers, in my opinion, have swung over from the idea that this is a perilous feature indeed, and maybe they can wrestle the newsprint demons to the ground and go on with life as it should be.

And then, secondly, we have things like branding applications, which are the more interesting way to view this Net, rather than just looking at it as a medium that has content. Let's just translate our own body of experience into this, because our own body of experience is as a medium to talk to people. What we're really talking about here is not just a medium; we [are] talking about what is actually an application platform, a platform connected to a medium that runs software.

And so we see things like Federal Express letting people call and not going to headsets, and banking people really moving hard to have you do your transactions, and Ticketron is really moving hard to have you call up and book tickets electronically, and the reservationists won't be far behind. In the *Yellow Pages* — people are positioning themselves to get out of the printed *Yellow Pages*. Lands End has come up with a catalog, and we're seeing all the catalog companies seeing the economics [of this]. PeaPod is delivering groceries to the home.

In an agency sense, we woke up one day and said "Here's our old funnel," — I pulled this right out of the old Forrester report, which is a good report of what the Internet is — and it said, "Well, here is how it works. What you have is an awareness, an awareness like we have of television, radio and print." I'm sure that most of you people are aware of this "funnel" concept; this is a top/down presentation.

And — if you will move closer — through seminars we give them the trade shows, and we give them the literature and we get them to go on the Internet to the Home Page and then

we get them to the store and we get them to order, and we get a salesperson in there to actually extract an order from the fully-aware and cognizant consumer.

The thing that is the most unique here is... Well, wait a minute. We have awareness, we have browsing and exploring, and all of a sudden you are exposed to ads and companies that you may not have heard of. We're out there with awareness, and I open this thing up and it starts to behave like a direct mail piece, it's got a call to action, it's got offers, it's got testimonials, it's got everything in it. Hold on, it's starting to look a whole lot like, maybe, literature. I've got all the specs, I've got all the white papers, all the stuff I need to buy, all the comparisons, and right now it's starting to look like a store. It's a kiosk, [it's] got demonstrating, I can download stuff and it goes to the customers.

So what we're trying to do, as an agency, and what we're trying to say is that this Internet won't sit still and behave as one thing, and it won't let us define it as one thing, it just wants to meander around and do a lot of stuff.

And what this means to agencies and to clients is fairly interesting here. Using the old "15 year, all things are linear" model, in around 1980, according to [Bozell] members, marcom expenditures — being 100% of marcom expenditures, although most of our clients' marcom expenditures never hit 100%, and advertising in 1980 was a simpler, better world — 70% of the marcom budget was advertising, 30% was everything else. In 1995 — and these are our parent company numbers, more on the order of that 100% marcom — 40% is advertising, as we call it in media, that reaches people in a semi-intrusive way, and 60% is other things.

And what has grown, the two factors that have caused it to change, are that one, the money has gone somewhere to be measured and so direct mail and direct response, and coupon programs and promotion have gotten a disproportionate share of the ad dollar, because all these dollars want to go to where something can happen.

We have, in the computer business, a constant battle to kind of try and hold branding dollars in the product branding area, because the company knows that if they load all those dollars into the circulars for "best buys" in the computer product stores they'll actually be able to count products that move — and people like to be able to count products that move with their ad dollar.

Secondly is that organizations are changing and brands are changing and organizations are driving decisions further down, and so you have people who have products to run and don't have a promotional budget big enough to aggregate an ad campaign — but they have a promotional budget big enough to promote a sales force with, or to run a seminar program, or to hand out T-shirts, mugs and hats.

In fact, today the T-shirt, mug and hat part of the advertising business is as large in billing as the print part of the advertising business, which I think means it's not only a medium, but a large and an extra-large.

The Internet is nice for us as an agency, but it changes our realm because not only do we have the MIS people talking to us and the PR people talking to us and the product people talking to us and the sales people talking to us and the channel people talking to us... but we're able to go out on the Internet and bring up promotions that are departmental in nature or bring up things that can be specifically tailored to the individual groups. Who is this medium for? It is viewed with great trepidation at our organization, our parent company. I enjoy it. They're excited by the future, kind of like "As long as it happens after I collect my retirement." But they have great trepidation about the future arriving next week and screwing up the TV business, the radio business and the print business. In New York we have to deal with this.

One way to deal with this is to divide the world into groups of two. I have always maintained and believed that there are only two kinds of people in this world — those that

divide the world into groups of two and those who don't. I was proven mathematically wrong — there are three kinds of people in the world: those who can do math and those who can't.

The two that I divide the world into are couch potatoes and interactives. I'll take this extreme and I'll say that we are not going to change the person who watches television into becoming an interactive user in the near future. It's just not going to happen. We all go through our moments of wanting to be a couch potato.

I will make the argument that I do not want to sit and argue about what the ending of *Frasier* should be. I like the way *Frasier* is written. I want them to send it to me, I'll watch the commercials that come with it, and when I'm sitting down and watching television I want to do that. And by the way, that end of the spectrum is populated with a lot of people who consume a lot of media, who watch a lot of television and listen to a lot of radio, and they don't use computers very much.

If they do use computers they're what we call in the business, "directed users," which means they're trained to fill in a form on the computer. They're meter readers; you can't drive without touching a computer, so we're all basically operating 280 horsepower computers. This is the Silicon Valley view, and in fact the computer component in the cost of cars is passing the engine component. We like that. It makes our business good. But at the other end is this whole new class of people, and I will give you a demonstration from my focus group, which I'm calling the "interactives," and the interactives are this class of people who are on-line and [know how to use computers in their daily lives to control and manage their time.

You have to understand the way they use the computer in order to understand how to extend your brands to them. I don't believe in trying to convert television watchers into interactive people. When the choir has more money, which the interactives do, and when it's more influential, which the interactive demographic is, then it's more motivated, which they are. You should definitely preach to the choir and let the rest of the people take care of themselves. The Internet is a medium, and it's going to be like print, radio, TV. Or is it a platform? Is it a computer that people use? I'm coming to the belief, through our work, that our interactive customers don't want content, they want time. What they're using computers for is to manage and control their time.

Content may be part of it, but they're just not translating [inaudible] from a medium before. Here is a happy user's computer; so where does this computer go in a day? People are trying to reach customers on their computer as their work. There's word processing, which is Internet issues and poppe.com strategy. They might have presentations that they're doing because that comes over their computers; they may have a calendar — which is [another way], through calendars and utilities, how people manage their day — so up comes a calendar. They may have a database to keep all the people in contact with what they do. You're familiar with all these applications.

There's the one for [Scott Heiferman] at Interactive, who is making the SRDS of Internet sites, and someone may now actually go to an advertising agency. What just happened here is that the Internet has done something — I'm on my computer doing all my stuff, which may come to me at my home or at my office, and all of a sudden I've kind of lost track of whether it's on my disk drive or the office disk drive or the world's disk drive, and that's going to become increasingly the case. I just know it's all there when I want it.

This is different from CD-ROMs, where you have to go out and mount them up, and different than proprietary services where you have to log on. This is a digitally connected computer that sends off packets when you're ready and doesn't when you're not, and makes the world look like your hard disk. What happens on the *San Jose Mercury News* is one of the most interesting anecdotes.

While I was at the Publishers 2010 Conference, we were talking about advertising and banners. As you know, I'm not sure, but one of the things we're learning about advertising is that about 5% or 10% of the ad banners sold by my account are representing Netscape and Playboy and a few other news sites that are coming up. I think that Netscape will probably pass 15 or 20 million dollars in paid ad revenues for ad banners. The *San Jose News* found out that people are more interested in the Help Wanted, but now the *San Jose News* has to worry about some Silicon Valley start-up that has created an on-line recruiting agency for high-tech people and is driving at the heart of the biggest revenue section of the paper.

That's the area that's getting the most readership, and it's getting a bit confusing. If one of the best read sections is the Want Ads, why don't we sell ad banners on the want ads?

[Tape change]

David Carlick: No, really. PeaPod is a start-up and Yahoo is a start-up and Architext is a start-up. We've got several venture start-ups who are looking to advertising revenues to build their brand, and these are services that are being delivered over the Internet and they are, for the most part, promoting themselves with advertising on the Internet by exchanging banners with other sites.

In a sense, we go out and build a brand by building up a core customer base and getting people to like it, and then getting it promoted; and then advertising shows us that brand, usually 2 or 3 years after it's been running and well after it's been established in a community and in the buyer community and in the channel community. Certainly it's important, and then we start in the image of brand building.

In fact, the most expensive and catastrophic start-ups in Silicon Valley history have been ones that have tried to build brand before the customer or marketplace had really defined why they wanted that product to begin with. So it's much more logical when you're taking things like that to do more research and development. Netscape is on their third brand ID, and more power to them. If they stuck with the traditional idea to stay with their original logo and image, that wouldn't have been appropriate for what they're trying to do right now.

I want to ask a question to this morning's panel, as we deal with crossing political boundaries and different legalities in controlling issues. For instance, that ad there or that page there would not be allowed in some places because they don't allow competitive advertising. On the other hand, the idea of putting up a server in the U.S. for U.S. customers, and a server in another country for their customers is a bit naive, because as customers get more sophisticated and more cynical they're going to say, "Are they telling me what I want to hear, are they telling people in other parts of the world?"

M: [inaudible]

David Carlick: The high-tech business is with companies that build their global market by giving the volume to compete in the U.S. market, and then making margins that are just absolutely unholy around the world. And this is a big problem, because pricing starts to leak out.

We will, in a sense, start to see a global marketplace, and it's going to be a problem. I think it's actually going to be a solution; it'll open up more markets than it closes, but being able to get \$6,000 for a computer you get in the U.S. for \$2,000, or \$50,000 for a car in the U.S. that you sell in Germany for \$30,000 will sort of go away, won't it?

M: What kind of pain do you see as that transition takes place?

David Carlick: Actually, I see not just that, but an immense amount of pain in the restructuring of the entire sales channel of companies as they experiment with this. We have companies that are sold through multiple distributors, all with different prices, all that serve different areas. The auto dealer channel — I keep coming back to that, but it's all a product we know and understand — is one that is perilously poised on the brink of an abyss as to how people are going to buy these, because a high percentage of cars are being sold through brokers.

I think the [inaudible] started in Houston, and by the way, that is a good one. I like that. I have one that I'm starting. I'm going to go offshore, and this is the last time you'll see me at one of these conventions, because when I get my site up I will be so wealthy... I'm going to charge \$10, you send me your naked pictures and you will streak the Net. I will send you back an e-mail when your pictures will be up for Net-streaking and you'll be up for five minutes — unless it's for a birthday or anniversary, in which case it's \$25 and I will then have millions of people mailing in naked pictures.

We'll have categories like Net-streaking, full frontal view Net-streaking while not looking, and I will actually have people paying me to work for me because all they'll be doing is scanning in pictures and putting it on the files. It's going to be a great business. There's all this money in the mail for this site, so this is the last time you'll see me; but I can't do it in America.

M: Speaking of cross-country issues, I work for a company that sells consumer drug products, and as we venture out into the Net we have a lot of questions about the kinds of claims you can make for a product. You can make certain claims for a product in the U.S. that you can't make in Europe, and vice versa. And, of course, whatever you're putting out there is going to be seen worldwide. We can see an advantage in that, because we could put the message somewhere else in the hopes that our American consumers can see it. I just wondered if you're familiar with any of the laws and any of issues surrounding this point.

David Carlick: The bad news about all this freedom is that the Internet is going to become the lawyer's right-to-work act of 1997. My opinion on the subject has always been "Why is it that lawyers have to wear ties?" and the answer was explained to me by lawyers: "Because it's the only thing that keeps their foreskin from sliding up over their face." We're going to have a lot of these guys to deal with over the next period of time.

M: Could you speak to the production costs for establishing a Web site, and possibly give a rough line-item breakdown of where the money goes?

David Carlick: We're in competitive bids for the work that we do, and thankfully they're all getting more expensive as they go out of business or raise their prices. It's just a matter of hours, and so we learn it as we go along. A site like the Chrysler site, as we see it presently embodied, involves — outside of the brand management that was working on Chrysler — on the order of \$100,000 of time to bring the site up in this form, and about the typical \$3,000 a month to keep it running and keep it current.

We are currently suggesting to our clients that they budget more or less on whatever their budget is, assuming that budget is enough to accomplish reasonable things.

So you kind of do it half down and half for the rest of the year. In other words, if they're going to spend \$50,000 then we take \$25,000 to bring up the site, and then go to \$2,000 a month to keep it doing all the things it should be doing for the customers. Unless you have an automatic way that it is distributed to your customers, many companies in our business can simply use the Web directory as an 800 number, so that they're not concerned about driving

traffic to it. But if you are concerned about driving traffic, then the banners right now are selling on the order of 25 thousand per thousand.

You can buy the banners or work the banners and get on *Yahoo* and do it that way; there are some good companies doing that for a living. People are getting conversion rates from a tenth of a percent to a couple percent, which is just like direct response.

Andrew Jaffe: David, thank you for your time today.

Multimedia Director, Giant Step Productions

Andrew Jaffe: This is a bigger conference than we're used to running on this subject, but we still want to keep it informal. I hope some of you will join my panels as I create them. Our speakers are booked into two-hour blocks, but they really don't want to go on for two hours, so they're depending on us to form the content of their presentation by our questions during the second hour.

Matt — is Matt still there? Did those people pick up their messages or do you want me to read their names again? The other thing is that Matt Pollack, my associate there, put on your places an evaluation form. I wonder if this afternoon, you might fill it in what, give people ratings for their presentation, one to five, just so we have an idea how they sat with all of you. And then there's a couple of questions at the bottom. A little room for comments. If you're here for only one day, I'd appreciate you turning that in to Matt at the end of this session. If you're going to be with us tomorrow, you can keep your evaluation form. Put your name on it or not, if you feel like it, but we would like to know your title, the type of company you came from, so we know how different groups in the audience are reacting to this. We plan to do it, as I said, next year with Internet World and we want to make it as valuable as we can for all of you.

Our next two speakers participated in an earlier seminar that the 4-As, that I did in San Francisco, on crafting interactive messages that work. The Heneghan brothers — Adam has the sandy hair and Eric has a darker coloring. Otherwise, I think Eric tends to talk a bit more, but in this case, he may ask Adam to. He says this time, he's going to ask Adam to do more of the work.

Adam graduated from the University of Indiana, where he studied business. Eric went to the University of Iowa, where he studied English. In 1990, they decided to go into business together. Adam is 26 now and Eric is 28, so they were two years apart. I don't know whether I could've started a business with my brother, but maybe we have a lot to learn from them.

They started Giant Step Productions. Their first application was just a video. They claim it's the first video that's ever been done on a Mac. They made it for a wrestler who wanted one. With that money, they began working using computers to create training programs for John Deere and other clients, and then they migrated from that to doing marketing applications for Silicon Valley firms, including Radius.

In 1993, Leo Burnett suddenly woke up to interactive and digital marketing, and rather than trying to build a creative department from the ground up, if you will, internally, that did execute for their clients, they formed an exclusive alliance with Giant Step and asked the Heneghan brothers to move to their offices in Chicago and help them create applications for their client list, which as you know, is very impressive.

Since then, the brothers have created sites for Dewar's — these are Internet sites or other applications — Dewar's McDonald's, United, Marlboro and Oldsmobile, among others.

We heard from people today who know a lot about economic trends, technology trends. We just had a wonderful presentation by an excellent marketer who tried to explain branding to us.

But now we're getting down to people who actually do the work and know a lot about the creative issues involved in making these kinds of sites and other applications come alive.

With that introduction, I'd like to welcome back the Heneghan brothers.

Eric Heneghan: To clarify again, I'm Eric, the dimwitted one, but I'm also the better-looking one, so it paid off.

I'll give you a little more background about who we are and where we came from.

We started off in 1990. I wanted to be a film maker and my brother was doing graphic design, despite our majors. And we went to Mac World, right here in Boston, in 1990 to go see what people were doing with computers. We had grown up with them, and as they were evolving, I guess we kind of evolved with it. And we came to see specifically what kind of video tools were out there. And there was this crazy guy, whose name is Joe Sparks, and I'll do a little plug for him, since the game that he's been working on since 1990 just came out last week.

This is first guy that ever put an application on a CD-ROM, as far as for entertainment purposes. It was being used, at the time, to archive databases and everything, and this crazy guy put on this game — "interactive cinema," is what he was calling it — and it was called *Spaceship Warlock*, if anyone has ever seen it. We were immediately taken by this whole medium and excited by it. And he just came out with a game last week. I'll plug him again.

Five years he's been working on this thing. It's the most intense, interactive multimedia experience you'll ever see. It's called *Total Distortion*. I got an e-mail the other day from his company that it came out Friday.

Having seen that, we decided we wanted to start a company doing this. And, as I said, the first thing we did do was a videotape using traditional media, because nobody knew what we were talking about when we tried to sell our services. They scratched their heads when we told them about on-line services and the Internet, even though there was no graphically-used interface at the time; no browser for the WorldWide Web, but there were commercial on-line services.

And so we started doing a lot of this work, mainly for corporations — a lot of training stuff — and then started developing marketing materials for [inaudible] and graphic companies who still, even today, I think, are very much in the forefront. If there's any marketing to be learned or advertising to be learned from doing interactive multimedia, it is from all the [inaudible] and graphic firms, since they are not only creating the software and applications in the whole industry, but they've also been utilizing it longer and have done it in creative ways.

So, anyhow, what ended up happening is we ended up talking to several ad agencies within Chicago. We ended up moving to the city and ended up teamed up with Leo Burnett, who had a very intelligent marketing group — which I think is important for anybody that's trying to do this in advertising, to not only have the smart marketing people who are, first of all, willing to admit they don't know anything and then start to learn it, and who also have the intelligence of marketing and branding to bring to the party, which is something we knew nothing about and are just starting to learn about.

I'll give you a little definition as well as to what our strategy is at Leo Burnett, because it'll give a little framework as to why it is we are creating the things we're about to show you and where it is we think we're headed, and then we'll show you some examples and hope that after that, it'll open up some dialogue and we can talk about some of these things.

At Leo Burnett, we have pretty basic ideas of the strategy and marketing ideas. We try to break it down to its lowest form, because it can get complicated and in all the complication

and technology you don't get to the basic issues when you're talking to a client or selling any idea or doing any kind of marketing.

The first thing is that we recognize this new medium as the fourth revolution — you know, the fourth communication revolution, starting with print, then radio, then television. Now we're going to this fourth one. Like any other communication or form of communication, none of them have ever wiped out another one. Print is still around; we still have the printed page, magazines and books. In fact, we like to say that probably the people making the most money right now off interactive stuff is the press who writes the magazines and the books all about it and the conferences. They're the people making the money off it right now.

Basically, what we do after we recognized this fourth communication revolution is we like to break it down into what makes it different. And the biggest difference with this one is you're combining the other three mediums and adding interactivity. I know this is a pretty savvy group, so bear with me while I go through all this, but in the past we had to explain a lot of this stuff.

So, we'll go on to the next slide — or I should say, the next page, since we're doing the *Netscape*. It's better than *Persuasion*. And basically, for interactive marketing, what we've had to do for all our clients, as well as for ourselves, is give a definition. I think it's interesting that we all still define it, because we're all still struggling to define what this medium is. In its most basic form — and we still have stuck by this since day one — we define it as two-way, real-time, addressable communication combined with rich digital content.

What's interesting about that right now is these things, while they exist, don't necessarily exist together yet. It's not a cohesive thing that's converged, this two-way, real-time, addressable communication. The most obvious thing is commercial on-line services, as well as the excitement of the Internet and its growth and what it's doing; the rich digital content being CD-ROMs and floppies, because you can't really deliver over the bandwidth yet the kind of content or creative content that the CD-ROM can deliver, and vice versa — you can't have the two-way communication on the CD-ROM.

What we're really looking towards, and I think everybody is, even if you look at the new *Netscape 2.0*, is the point where those two converge. Having said that, it's an important point, because as we continue through this presentation we'll show you the other things we're doing on CD-ROM and why it's important not to ignore those and only be focused on the Internet right now. If you look at all signs of what deals are being made between Netscape and, let's say, Macromedia with *Director* and tools like that, with applets that are being created, like *Hot Java*, you're going to be able to deliver the CD-ROM kind of functionality once the bandwidth is there. And it's important to have those skills, not only creatively from a marketing standpoint but also from a production standpoint. And I think a lot of people are overlooking that right now.

A lot of people are specifically focusing on creating HTML pages and everything and overlooking working to become a very complex, confusing thing to create. So it's important to look at both sides of it. As I say, we all have our own way of defining it.

How is advertising primarily changing with this new medium and the way we're defining it? The way it's primarily changing — and this is the most basic way everybody talks about — it's push to pull, from an invitation to intrusion. The metaphor that we've come up with and have been using over and over and over — I think it still fits — is removing from a mass media communication standpoint from a true leader to the traveling salesman.

That's true that leaders in the past on television and more passive media will yell at a crowd. And it's a large crowd, and because of that you're a hundred yards away. We're yelling; the statement is very general, because it's a large group of people and we don't know who we're talking to. It's also simple for that very reason, and because you're intruding on people,

whereas if you're a traveling salesman you're talking to individuals, you're going door to door. It's a dialogue. It's not yelling and screaming at someone, just shouting one way, it's a conversation that happens. It's customized, because you're now talking to an individual and their needs might be different, and you can focus more on that. It's in-depth and it's also invitational as opposed to intrusive.

Moving on from that, we built this business model at Burnett, and the way we look at this medium is that there are two camps right now. That's starting to change and that's starting to meld, and I'm sure it will as time goes on. But there's the evolution versus revolution. We'd like to think of ourselves as the revolutionary part of Leo Burnett, which is kind of fun, because they let us get away with it. And they're kind of the evolutionary part that's trying to grow into this new medium.

And you hear these arguments all the time when you go to conferences, when you read *Wired*, when you go through *Hot Wired*, anything. There's these two camps that argue back and forth. There are those people who say it's just another media, and you have the revolutionaries yelling, "It's not media." Ad agencies that are capable versus ad agencies that are completely dead. It's a whole new kind of agency.

You hear that argument a lot, grafted-on versus rethinking everything. Clout matters versus sizes of disadvantage. Wait for the shake-out versus let's do it now, and central control versus anarchy. So as anarchists, we'll show you some of the things we've created within this evolutionary setting.

So, the first thing we're going to show is — since this is an Internet conference — a site that just went up recently that we did for Maytag. And one of the questions we all asked ourselves before doing it is, why Maytag? Why put them up on the Internet? To answer that question, I'll just tell you where it all started from. When we first got to Leo Burnett, the big hype among ad agencies was interactive television; that's all you heard about. Everybody was making deals, the Time Warner site was going to be up in no time, thousands of homes to millions in no time.

Those of you who are here from ad agencies, you know you were visited by every single little Baby Bell company or cable company telling you about these interactive TV sites that were going to be up in homes. I think the numbers right now should be in the millions, but I think it's still under a thousand.

Maytag was interested in getting involved in one of these, and we said — the way we've approached all interactive advertising that we do — we said, "Well, what is the marketing [problem] you're trying solve and then let's find a medium, if it fits at all."

And what they did want, one of the things they wanted to do was get involved with this medium as quickly as possible so they would have the learning and thinking of being a leader as opposed to a follower. And I think there's a big advantage to doing so. Not only do you learn things internally — and I'll talk a little bit more about that — but it's an essential part of doing advertising in this medium, because so much is no longer with the ad agency but also internally.

And the main reason for that is you now have this two-way dialogue happening and are these brands ready to give up that dialogue completely to the ad agency or do they still want to be part of that conversation? How do they handle it? Usually that means their customer service. So, for Maytag, what made sense was they wanted, basically, just to have their information out there in a digital form for people to be able to go access that. And nobody was kidding themselves that they were going to go there to be entertained; you're going there if you're looking for an appliance, whether you're building a home, whether you're a construction person or whether you're a consumer looking for something.

And also, one of the important things is to stay within brand character, which is why we work with the traditional creatives at the ad agency that work on these clients. So, some of the

things you'll see on the Home Page, "Old Lonely," who's obviously the brand character and "Home Dependability," which has always been the tag line for years that Burnett created. And some of the areas we have there are specifically for consumers, as well as people who are doing construction.

For instance, the product specs and remodeling is an area where they can go in and get specs if they are doing construction. And there's more information here than you would ever want to know about any appliance. Every piece of print, all the text, all the photographs, everything is up here, which is another important part, we think, to putting up any site. If you're a big company and people are looking for information, don't just put a page up that says "Under Construction" and it's going to be here soon. We didn't put this up. We worked on it for a month before it ever went up and we made sure it was complete, without the construction, and all the information was there.

Adam Heneghan: One of the things that we also try to do from a production standpoint is to try to keep all the graphics in a digital realm. We try to create them all digitally and have them so we can basically update the site very quickly and easily without having to go back and find the original illustrations and alter them that way. We just try to keep everything so that if a change needs to be made, we can make it that day and get it back up there. This is important to keep in mind with Web sites, because there is so much information, and you'll find that a lot of the information is going to be changing often. In addition to that, you may make a lot of mistakes just because of the sheer amount of information that's being put up there.

I mean, this represents every piece of printed material that Maytag has, and they worked on that for years before getting it out, so there really is a lot of information behind this site.

Eric Heneghan: We're going to spare you from every page, though.

Adam Heneghan: Now we'll move on to the next site. This is something that really makes sense for this client, because it's where their business is headed. You may have seen some of the other forms that they are already creating. The client — well, actually, before we go there, I very quickly want to click on some of these pictures and stuff. One thing I do want to mention before we push on is that the illustrations we use, from a technical aspect or creative issue, as you all know and are all painfully aware, depending on how you're hooked up to the Internet it can be very slow for the consumer.

The best thing you can do when the consumer is trying to get information — which, in my opinion, is what a lot of people are using the Internet for right now, to gather information — is that you want to do it in an attractive way. You want to do it in a way that speaks well for your brand. But I think you also want to do it in such a way that you don't frustrate them.

One reason we pick illustrations is we always try to shoot for the bottom-line consumer. More than likely, the most colors they're going to have is 256, you know, [inaudible] color. Illustrations look better in color, as opposed to putting photographs up. It might look great at your ad agency, but not great for the consumer out there. And it also makes it a much quicker download. The graphic files are smaller because we are trying to deal with fewer colors.

So, having said that, I want to move on to the next site, United Airlines. This client it obviously makes perfect sense for, where the digital media is going and for their business and what they're trying to do. United, in the future — and they already are testing this out on CompuServe, for those of you who are on a commercial on-line service, and it's about to go up on Microsoft Network.

They are starting a test doing reservations, mileage-plus, checking your flights. Basically, any information you'd want. And the speaker before this previously talked about the pains, I

think, not only for the consumer, where you call and are trying to get some information and you're put on hold and you have to wait for an operator. To be able to go get information right away — and businesses want that, I think, as much as anybody, and that they don't have to staff up to have people at the other end of the phone, they don't have to pay for the 800-number and having you input all the information. And in some cases, if you're on a commercial on-line service, making money off it, according to the deal you make with the commercial on-line service, as opposed to what you're paying them now.

Adam Heneghan: Again, not to interrupt you, but one of the other things that's interesting about this site, which we sort of initially agreed to and it became a bigger deal than we thought, was to have two versions of the site: one a high-bandwidth and one a low-bandwidth area. We can show you examples of both of those, but we ended up almost creating two sites, just because of agreeing to do that. And it was something we thought we had to do, because of people getting on an AOL and other browsers that are available now.

So, that's another thing to keep in mind, is if you are going to be working on these sites, it makes sense to develop the lowest common denominator and maybe do it across the board, as opposed to having two versions.

Eric Heneghan: To clarify that, for those of you who haven't been on the Internet using a commercial on-line service browser, if you're creating towards *Netscape* — which is something we try to do, as well as almost everybody else out there, because *Netscape* supposedly right now dominates 80% of the browser market. The commercial on-line services don't have the same kind of software written within them, so they don't format your pages correctly and they end up not looking the way you created them.

So, this is the "Friendly Sky" line that's been created.

And, again, working with the creatives at Leo Burnett, who work on the account, we stayed with the brand character, which is the employee-owners of United. You have a universal metaphor, since they are worldwide and fly around the world now. And you basically click on some of the employees, who are real employees, and who will be changing from time to time, probably every two weeks or month or so, and it takes you into that information.

Again, there's more information here. One thing we try to focus on the Internet with our clients is, I think, that really what people are using it for now is gathering information. At some point it will become entertaining, but for that medium right now a lot of people choose other types of media to be entertained. There are some things out there that are obviously very well done, and I think that's going to increase.

So, basically, I'll click in here and we'll show you the rest of the interface. There's a little slow connection here.

Staying within the interface with the employee-owners, those people on there become the icons throughout the rest of the site for what they represent, like "News from United." And they stay down the side as buttons linking you to the other areas, as well as within the hypertext, which is within the copy. And at the bottom of every page we also have some of the things that are under "News from United," the subcategories.

And we also have at the bottom of every single page the foreign destination or somewhere within the country that United flies to. It gives you a time for that city right now, as well as the latitude and longitude where that destination is.

We'll show you a little bit how the interface works when you do click on a subcategory. As you can see, at the top of the page, the "News from United" becomes not highlighted anymore and the press releases do let you near a subcategory. And you can jump back and forth. Like the Maytag site, we try to make it so you can go to any information you want from

anywhere within. You don't get lost as you head into subcategories. You don't get lost, trapped down there. You can basically find your way anywhere within the site for any information you want.

So, having shown both these sites — the cities at the bottom always come in randomly. Some of the other things we've got in there — we can try it, depending on how this connection works — is basically a database search, as well as a searching function. Adam, you might want to talk about that within the site.

Adam Heneghan: Initially, we designed this site for three stages in order to accommodate what United wanted to do right now, as well as let them grow into it as far as reservations and ticketing on-line. We developed some areas where you can do searches on flights, whether you know what city you're leaving from and arriving to. It'll bring back that information.

Unfortunately, those kinds of applications are still very difficult to do on the Internet. They require some high-level programming, and it's the type of thing that we hope to see become more prevalent on a lot of sites. But again, it is something that ends up being a lot bigger deal, especially with information changing so rapidly, like in United where their schedules change almost all the time.

Eric Heneghan: You also have a search feature at the top of the page for the site itself.

Adam Heneghan: I heard somebody mention Architext earlier, but there is [inaudible] using their search engine to do a complete search of the site. It's interesting, because they have a search engine that allows you to search, based on concept versus on just specific words, which is interesting. You can ask for the most comfortable seats or something and it'll find the most comfortable seats on the planes. It's pretty wild.

Eric Heneghan: Or any information, even its laundry, if it's doing dirty laundry. It'll basically rank them among what makes the most sense of what you were looking for based on that concept.

And the other problem with a big company like this is anytime you start to create stuff like this, it involves working with their IS department or anybody who's currently managing databases. In some of these companies, the databases are obviously just huge amounts of information there and they're changing constantly. That becomes a huge challenge.

Here's the search that will do concepts, as well as words.

M: [inaudible]

Eric Heneghan: Oh, no. This may not work. Oops. No, it said any information you submit will be insecure.

M: [inaudible]

Eric Heneghan: It's still looking, though. There we go. It found eight things.

Adam Heneghan: Also, it'll rate it based on —

Eric Heneghan: It rates the stars, see.

Adam Heneghan: Also, you can do a summary of the rest — oh, I'm sorry. You can also do a summary or you can summarize that page just by clicking on the "S." It'll give you a quick

summary of the page, which is nice. And you can also use that page to query the rest of the site, as an example, so anything else on the page would be similar to that one and would bring up and show you those pages, as well.

Eric Heneghan: Let's see what it came up with.

Adam Heneghan: "Roots."

Eric Heneghan: Did it? So this is the site that it took us to. And as you add more information — one of the other important things is that we're trying to create this in such a way — the Internet is obviously changing constantly. The tools are changing, your information as a company is going to change. So we try to build it in such a way that you can update that easily and keep adding to it as the tools change, as well as the information.

Now we're going to move on. We'll come back to more Internet stuff, but, as I mentioned earlier some of the things that we're also trying to do is continue on the course with some other media, like CD-ROMs and floppies, and I'll talk about how that's going to play on the Internet, especially with *Netscape 2.0*, which I don't know how many people here are familiar with. We'll get into a little of that. We'll show you some of the other examples that we have been doing: One is for Sony.

Adam Heneghan: And this is actually an interesting application. What we did initially — there was no way to do this across the Internet, and now with languages like VRML, which is Virtual Reality Media Language, it allows you to create 3-D objects on the Internet. They essentially developed the same application which we had to do on a floppy-based or a CD-ROM-based environment, and that's something that's becoming more compelling about using the Internet as a way of communicating. We'll show you that example.

Eric Heneghan: To give you a little history, the concept was created about two years ago and we started production on it about a year and a half ago. At the time, there weren't even CD-ROM drives out that [inaudible] put something on, so we wanted to do it on the floppy, as well as put it on the Internet on their Home Page and on commercial on-line services as a way to demo the Sony *Magic Link*, which some of you may have not seen, the personal digital assistant, kind of like the Apple *Newton*. And the concept behind the marketing problem was how do we demo this product that, at first, is only going to be used by earlier adopters — how you demo a product.

Basically, how do you demo a product that costs \$800? You're probably not going to build that many at first, even to demo to people. How do you get it across and let them try the product and see how it's different from other products out there? So, what we created was a virtual sampling which, in essence was a little, tiny file. We wanted it to be a quick demo. We kept it to 700K, which is fairly small, fits on a floppy, downloads fairly quickly and allows you to try the entire application — the entire hardware and application.

I want to hold the microphone near the speaker.

So, what basically happens here is you have an explanation at first of what the *Magic Link* is. A little intro. Sorry about this.

I'll try it one more time. For those of you who have seen this application, it just won — Communication Arts just had their first interactive contest, and it won the best interactive ad. Hopefully we'll get to see it. We basically created a 3-D model of the *Magic Link* that you can rotate 360 degrees any way you want and rotate it to any side, click on its sides, any of its features, its buttons, its hot spots, and it'll tell you exactly what the hot spot is.

We can't, unfortunately, show you the *Magic Link*, because of a little technical problem here. It's a brand-new *PowerBook*.

Basically, you rotate everything, click on any of the buttons in the hot spots and it will actually let you go into the application throughout the software, as well. It would be the same thing as going into the store and actually being able to sample the product.

M: [inaudible]

Eric Heneghan: Yes. It's on the Sony Home Page. If you go into "electronics," there's a *Magic Link* area there where you can download it. Once you actually click on it to zoom in, you can actually go try out the entire software. It's all hot. It either has the functionality of it or has an explanation. Why don't you go back to the desk, Adam, and see if things on the desk work just like they do [inaudible] the *Magic Link*, for those of you who have seen it, or are familiar with the product.

Since you couldn't actually see it within the application, let's see if we can launch it here. Because basically, it was a *QuickTime* movie that lets you access every single frame of it as you twirled it around. You had complete control over it. It's just a 3-D model. And, as Adam mentioned, in the future the way things are going — this is all built-in *Director*, by the way, which is something else that Netscape is building, is *Director* functionality and programs within *Netscape*, which is pretty exciting. It's in Version 2.0.

So, let's try one other one here and see if this works. Go to the Dewar's. This is something else that we did for Dewar's. This is a CD-ROM application that was put on what's called a [inaudible]. That's what they're calling them. I'm sure some of you have seen them. The one that we initially built it for was *Launch* magazine. What they're doing is putting their magazine anywhere, even bookshelves and computer software stores. They've started to become one and the same. *Launch*'s idea was to create kind of a *Rolling Stone* – *Spin*-type of magazine, where they actually go film an artist within the studio while they're recording, interview them and add those tidbits, as well as reviews and music you can hear and video clips that you can see. We're having it sponsored by advertising, so we did a Dewar's ad that is basically graffiti within their interface.

You can click on that billboard and it takes you into here. We have four different parts of the application. One is just the most obvious, a place to order merchandise, and since they have an on-line presence we'll be able to do it on-line. Right now it's an 800-number and order form that prints out. And we went along with the current print campaign, and the reason this was such a perfect application from a marketing standpoint is that Dewar's — if you seen the campaigns, especially in the Northeast, they're targeting people in 21 to 34, early adopters, kind of young, hip, trendy people, trying to get them to drink scotch since it has fallen into an older crowd. They're trying to make it exciting again; it's for young people.

So, we went along with the print campaign. We also took a traditional dog puzzle — I mean dog ad, sorry — and turned into one of those puzzles you get pissed off at and take a screwdriver to. We were thinking about building in some hidden keys that would turn it into a screwdriver, but... We have the time down at the bottom.

At some point they'll have an on-line presence. They'll be able to send the scores for a cap or T-shirt. We always hide things in the interface. You heard him when he clicked on the glass, it kind of jingled.

Now we'll try this one out and see if it works, because the *QuickTime* doesn't seem to be working on here. Let's see what happens.

So your taste in movies isn't all that's changed, and what we want to do is do like a bad B movie. At the time, the biggest thing on CD-ROM was *Myst*, and we wanted to try and play off its success — interactive cinema again. So, let's start it here and see if it works.

"Find the treasure bar and avoid the monster at all costs." So you're basically thrown into this 3-D city and you're running around trying to find the bar. You see the monster at the top. And the way you navigate is you can see at the bottom, it shows the directions you can go in. One thing that's interesting about this, is the media buy is done per megabyte, so you saw here the choice of going left or right. You decided to go right, and as a result of that we had to limit full-motion video and stuff because it was taking up too much space with the media buy. We did a bad move there.

"We regret to inform you you've been squashed like a bug; we invite you to try again." So we'll do the correct route here. If you look at his hand, he can go left or right. Show the left or right — well, you can go either direction and it shows you on the screen. See over here on the left, that building there is the Leo Burnett building which — we blew it up, actually, with the monsters. It's kind of fun. It's good on here. We'll just take you to the correct path to the tavern.

Basically, you're finally safe and you have a 360-degree bar you can navigate through here. These are the kinds of things that you'll be able to do, hopefully, sometime on the Internet as bandwidth increases. And the tools, like I said, are starting to get there. We have a lot of fun with it, but it is also the whole new level of doing things. That bar, for instance, is a 3-D model we created. For those of you who know anything about building 3-D models, it's actually made up of 2400 different 3-D models within there. Everything down from screws to nuts and everything else.

So, that's an idea of some of the stuff we're doing on CD-ROM. And like I said, we encourage everybody to keep playing at both these medias, because they are converging more and more.

Netscape 2.0, and I briefly touched on it, has just come out. It's the new browser, and they're building in plug-ins. I don't know if this means anything to anybody, but what that's going to allow you to do is other people out there, like people who created *Director* — which is how we created those other two ads — or people like *Java* are creating basically a language, so you can write these plug-ins. And what plug-ins are going to allow you to do is have some other creative person out there, while Netscape's worrying about making a browser that works, creating new applications nobody's thought of yet. They've created an open architecture or language that is open for anybody to go create anything they can think of, and add that functionality within *Netscape*. That's a pretty exciting thing.

For those of you who know something about the graphics world, *Kai's Power Tools*. Those are plug-ins written for *PhotoShop* who — he's added a whole new kind of graphic element to *PhotoShop* just by being able to do that. You know *Hot Java*, which everybody keeps talking about, is being built into that for those kinds of browsers.

Well, having said that, we're going to go to two more examples very quickly. I just want to go to America Online first. The reason I want to show these examples — and one is an on-line service and the other is a CD-ROM-based product that's going to be coming out early next year — is the branding across different types of distribution; one being the on-line services, the CD-ROM, and also, we have an Internet example, showing you those three and how the branding can work across all those different types of distribution.

We'll start with America Online here. I'll show you some of the other things we're doing for clients. It's interesting, too, because everybody is also targeting towards Internet now and not maybe looking at — that a commercial on-line service might make sense for certain clients, depending who they are and what their marketing objective is. Two of the clients that

we've put on there, McDonald's and Oldsmobile, we'll show you. And we're doing things across all the different media. Probably the client that has done the most of that is Oldsmobile.

The first thing we'll show you is something we're currently doing for McDonald's. Their marketing objective was to start playing in this realm, and the commercial on-line service seemed similar to where they wanted to be. It's already kind of a community. Some of the ways we like to describe on-line services of the Internet is the on-line services are the nice, neat suburbs — and the Internet is the big, bad city. It is interesting, because they can have advertising right at the front, they buy media. Somebody else is in control. They have a lot more control over the content being on there.

We're having all kinds of problems here.

So, with McDonald's, what's interesting for them — and these are some of the issues a lot of clients are having — is all of a sudden you're having a two-way communication happening. How comfortable are clients in this new world? Right now, they're not very comfortable. The Oldsmobile example we'll show you, for those of you who have seen it, it is interesting in that they've opened up communication lines, which is where this world is going. McDonald's, who's been sued for spilled coffee or anything else, obviously is not as comfortable with this new medium and opening up those lines of communication. And, like any big company — and I think it's true of anybody — they are staffing up to be able to handle that demand, whether it be customer service issues or anything like that.

I think it's very frustrating for a consumer to go into an area that you're accustomed to and then having that two-way communication happening, going into a big market and not being allowed to do that, but only be able to just go through information. There's nothing more frustrating than having a place a company says you can send e-mail and not hearing anything back. I think people like that miss the point. So McDonald's created for parents to go in since McDonald's feels that it is a family place and a place where a lot of families visit.

It's also part of a direct-mail campaign that's been very successful for them called "McMoms," and the concept behind it is just to create a place where parents can go. And they're not asking for anything; it's not a big sell, it's just working to build that, to enhance that relationship with those families. It's a place where parents can go talk to other parents, leave tips and information. They also have experts on there all during the week about parenting and raising issues like that and being able to talk to the consumer.

Adam Heneghan: The other thing, as well, is that this is also done on the Microsoft Network, so it's both on America Online and the Microsoft Network. Again, because all the art was created in-house, we kept that in mind, and when the illustrator gave it to us, we were able to disseminate it to both Microsoft and to America Online.

M: [inaudible]

Eric Heneghan: The other client that we'll show you on here — and I'll just get into that so we don't have to wait any longer — is Oldsmobile. If not, we'll just push on. The other one that I'll talk about very quickly is to give you a little brief example of Oldsmobile.

What we created for them was a site where they really are opening up the floodgate. They've created a message board where anybody can go in and say anything they want about their products; and probably the reason they did that is we were able to show them that these conversation areas are already happening. They can either join the conversation or let it happen.

These automobile conversations were already on-line. The Internet already has a forum where you can go talk about these things. You can either be in there standing up for your brand

and standing up for your products or you can just [inaudible], and so they've actually created a message board where they have people who are managing it. They get back to you probably within six hours at the most. If you're having a problem with your car, they get back to you and tell you how to fix it — they work to fix it for you. Everybody has seen this publicly, as well.

I think that in the past a lot of the American car companies had a bad perception of not caring about the customers and not giving them the kind of service they needed. This is one way for them to show them, as well as showing that they have moved into this new world and that they are technically savvy.

In the marketplace and in the commercial on-line services they always have highlighted things. In some cases it is Oldsmobile, in some cases McDonald's. The other thing we did in the past with Oldsmobile, in order to drive traffic through there from an entertainment standpoint — whether it was car companies or whoever it was, the advertising was creating the soaps and the Miss America show, and a lot of the entertainment that was on there — we created an area called "Celebrity Circle," at a time where people weren't really having celebrities on there. And basically it's "The Tonight Show." Every single weeknight we have a celebrity on there that you can go talk to for two hours.

I wonder if McDonald's is down there, "McFamily?" Oh, you know what? Don't do it.

This is basically the AOL site. The interface are the windows, the different parts of the family. I want to just go into one of the chat areas like "Craft Ideas" over on the right. It's just an area where several ideas are being shared by other parents. You can click on the buttons to bring up the different subjects, as well as go to a message board down in the right corner. They will take you to "Craft Ideas" and "Shared Thoughts" down there. Down below. You can send a tip to the editor.

One thing they wanted to do, since they didn't feel comfortable just opening up the message board, is treat this like a letter to the editor. The best ones are posted up there for everybody to read, and here's some examples that mothers have sent in of craft ideas. There's also an area on here where we can find out what the Happy Meal is and sell marketing information like that, as well as customer service relations where you can go talk to them about any concerns you might have.

Having said that, we'll go to Oldsmobile.

M: [inaudible]

Eric Heneghan: Yes. That was one thing that was the most interesting; the first time we ever put McDonald's up there was [inaudible] area, and it actually was one of the most highly-visited sites.

This, for instance, is Oldsmobile. I don't have the exact numbers and I don't think I'm allowed to give them out, but I can tell you that for Oldsmobile, night is the most popular time in what they're considering prime-time hours. Part of the reason is the "Celebrity Circle." McDonald's, too. It's pretty shocking. People are attracted to brands, which wasn't something we were sure about on on-line service. They definitely are.

[Tape change]

Eric Heneghan: So, here you see tonight Monday's "Celebrity Circle" — Jennifer Grey, whoever that is. Must be a director or something; I guess I'm too young, I don't know. So, there's "Celebrity Circle." There's transcripts here. We can read past transcripts of past stars, as well as photos.

But the part I wanted to show you that I think is the most interesting — besides the Oldsmobile showroom where you can go find out about any of the cars and see pictures of the interiors, the exteriors, how the cars work — is that you can download articles from *Car and Driver*, *Road and Track*, everything that's out there about their cars.

We'll go to "Olds Tack" here which, like I say, is one of the gutsiest things I've seen a marketer do on-line, whether it be the Internet or a commercial on-line service.

Does anybody have any questions about any of this?

M: [inaudible]

Eric Heneghan: It's always very interesting with any of these clients, because they're all so different, who you talk to. With Oldsmobile, for those of you who know who he is, [John Rock], who's the head of the company, actually came to a meeting. And in the first minute I don't think he had any idea what we were talking about. He picked it up within 15 minutes and the next thing I know he ended the meeting and said, "Let's go do it; why are we sitting around?" And that doesn't happen too often. He was very trusting about the whole thing, and I think that it's shown him it's paid off for them.

There are some interesting things in here, like a brochure. They can figure out right away if they want to send it to you or not by asking you questions. They're having you fill it out. They don't have to have the phones manned, like we discussed earlier. And I think it's paying off in even their image, and they're on there answering any questions and fixing any problems people have.

M: Another question: some people have complained about working with America Online, that they have so many limitations in what you can do.

Adam Heneghan: The most frustrating thing for me with working a commercial on-line service is that they don't give you any tools to go create these areas yourself. They're starting to. And there's nothing more frustrating than handing something off to somebody and having them tell you it's going to take so many months to go put this site up. I find it hard to believe it takes that long, for one thing, because in what you're doing you have limited graphics and everything. And not being able to have control over it yourself, I guess, is the most frustrating thing. You're having to depend on them.

Where they are starting to build tools, Microsoft Network, for those of you who are playing with that, has built a great tool called *BlackBird* to create areas within their site. It's pretty simple to use. It's coming out, I guess, the first quarter, it'll be available to people. We've been playing with it and it's fairly impressive for creating your own areas. And a lot of limitations, I think — it's a concern we have. We're the biggest advocates of the stuff.

We're incredibly excited about all of it, but a lot of the stuff is being so oversold. I think it's not only in the media but by people trying to sell the product and everything else that by the time the consumer, who's just reading about the stuff or just hearing it in the advertising, goes on there, I think if it's oversold you're going to disappoint them. If you just manage expectations, it's a pretty amazing thing.

M: [inaudible]

Eric Heneghan: That's where your media buyer comes in and that's where we've found it [inaudible] that is where some of these big companies come into importance, and if you have

savvy media people or even a client that can say, "Look what I'm bringing to you..." A lot of the deals I've seen actually get a cut of whatever money is spent in your area.

Why don't you go into one of these questions, Adam, why don't we just go to Olds "Aurora" here? And this is just some mail that people have put up there. "Hey, Olds, how about" — what's it say? Message in the Northstar, I mean, the Aurora engine 4 or 6-liter, stuff like this. People who go on there start arguing about foreign and domestic cars and when you have people standing up for your own product... Jim didn't blow it. Here's somebody standing up for the car. Somebody wrote something about it. "It is the tip of the iceberg. Look out. Here comes the new Oldsmobile." And you have consumers standing up for you like that, and the people who work for Oldsmobile are posting messages clearly saying that that's what they're doing.

So having shown the Oldsmobile area on America Online, we'll show you what we're doing for them cross-platform. We're doing stuff on CD-ROM, as well as an Internet site for them. The CD-ROM, the concept behind that — and we decided to do all these things at once when the initiative was launched. The CD-ROM was taking that Sony *Magic Link*, basically, and doing it with every single car. You can rotate the car, click on it to find the features about it and get the information you want about it.

And the CD-ROM is being placed on a program for mapping that we found already existed that didn't use the whole CD-ROM. They basically map all around the country, and it's going to be given to anybody who's a good customer or as an incentive to test-drive the car.

And, again, this is all in progress. Yeah, this is something that is being created. It's not actually done yet. They were nice enough to let us show it.

Those of you who are coming from ad agencies, that movie right there was actually just created by the art director who — it's his voice and everything and, obviously, we'll put in the real voice later. But he did just sit down at his computer and just decided to edit that in a way they probably would never get to at other times.

As opposed to going into a post house, he was given the software and he was able to edit it.

M: [inaudible]

Eric Heneghan: That's coming on the hard drive right now, but we're shooting for anyone with 180K.

What Adam's doing right now is he's navigating to the car. As you can see, he's actually — it's like *QuickTime VR*, basically, the software they wrote for the Sony *Magic Link*. And it also changes the big picture up above. You might ask, why are you doing that? The reason we have to do that is to rotate a big picture like that, a computer can't really handle it right now, so we're doing it with a small [inaudible]. And then when you go up to the big one, it actually has hot spots at the trunk, for instance. Click on and read about that. We'll do the engine and the interior, just to give you an idea.

So, we're also creating an Internet site for them. And that's basically some examples we just wanted to show you and hopefully that's opened up some questions you might have about any of it.

M: I have one question. I work for a bank and don't have anything quite as sexy to show as the Aurora; maybe something about as sexy as a Maytag washer, but one thing I'm interested in is that when you think of multimedia and interactivity, you think of something jazzy like that. What have you found in terms of copy treatment on-line or interactive? How has that changed from the traditional media?

Adam Heneghan: There was actually a great comment made... If we go to the Voyager site, which is on the Internet, there's actually a great essay a guy wrote about how we've thrown typography back about a thousand years by going on-line. Some of the things, I've actually see some software. Right now it's obviously awful, because the screens are unable to recreate some of it the way it should work. It is what [inaudible] what a printer does for us is it turn into Postscript and smooth out those fonts and everything, and this is done for us.

So what we're having to do a lot is create graphics, not treating the text as real type that's being downloaded in real-time, but more as a graphic that's being downloaded. The problem is that slows it down for the user. That's some of the ways around it. The other thing is being able to pick good fonts.

There are people out there designing fonts specifically for the screen that hopefully will improve that. Some of the other issues that I've actually seen is Microsoft is working on some software to work with their *BlackBird* that will actually create kind of a postscript within Microsoft Network to their type, and that'll come out in the first quarter. That is a huge problem a lot of people have, to answer your question.

M: [inaudible]

Adam Heneghan: By the way it's written? I think there's been a lot of studies done. The reading off the screen is not a very pleasant experience and most people tend not to. I think that'll improve as screens improve. Some of the things you guys may or may not have heard about is Bill Gates and these screens he's building that supposedly exist in his house.

They have all kinds of things, like a retinal scan, so they can see where you're reading and it'll move the page according to where you're reading so it looks like it's — you know, perfectly stays within your eye. And these screens also display artwork when they're not being used as television screens or computer screens. That's why he's buying up all the great artwork in the world, so he can display it almost as a screen-saver within a frame. So, I mean, those are some of the technologies that'll advance.

But, I think there's a lot less copy written, to be honest with you. I'm not sure how many people actually read on there. I do think there is a place where you want information like that. And the biggest thing about the copy is now you're able to navigate through it much more easily and the hypertext adds a whole new element to copy. I think that's an amazing thing, to have text back in the text, if someone wants it. It's kind of an exciting thing.

M: I just got asked this question: How many hits does the Maytag site get? Do you have an idea of how many people are...?

Adam Heneghan: The reason it'll get hits — and, I mean, everybody planned on it and planned how it was going to work — is that it's tied into all their print material as well as television stuff. They're going to start putting that address on there, so that if you are in the market for buying something... It just so happens I'd bought my first place and was looking for appliances when we were building it, so there's actually stuff there that I know nothing about. But everybody knows that's who's going to be hitting it. It's only been up for about a week and a half now, so I can't tell you what — we do have some software written that tracks that, tracks how many people are hitting it. But I don't have those figures yet.

M: Could you repeat the name of that context-sensitive search engine that was at United?

Adam Heneghan: The name of the company, I believe, is called Architext, and the name of the product is *On Target*; at least, that's the name of the beta release. I think, it's still beta. It's being used for *Hot Wired*. It's also under the Net Search button and *Netscape*, so...

M: [inaudible]

Adam Heneghan: We have built some message boards and United is intending on putting them there for talk about travel. The biggest concerns for any big company like this when you start to deal with it — that's one thing that's probably most frustrating, dealing with small companies like Silicon Valley companies, but you can understand their hesitancy to dive right in there. It's just the legal ramifications of having open message boards out there and having any kind of communication like that. But United is planning on doing that.

M: [inaudible]

Adam Heneghan: We've actually built several. The one that we built for United is just basically like a message board, similar to *Hot Wired*'s, some threads, and it'll probably be used for talk about travel. For most clients, I guess today there's just a hesitancy. Oldsmobile for sure will add that to their site when it goes up. That's still being developed. But it works so well for the commercial on-line service for them.

And there also are companies out there who are working on real-time chats for building a community. We've seen it and we've played with it. We haven't actually developed anything like that ourselves. Right now it seems to be a fairly difficult thing to navigate and also requires you to keep loading the page in order to keep pushing the information through. But, I know what you mean, and that's definitely something that I think everybody's looking into, is a way to grab a little bit more community-based feeling, like the on-line services would be.

M: [inaudible]

Adam Heneghan: The two examples that we showed: One, Maytag is actually being served [inaudible] and the other is United, which is going to be served by United through their [inaudible] department.

The other thing I'll mention about United, since I did about Oldsmobile, is that's something that's a work-in-progress too, and they were nice enough to let us show it. It's not actually up there yet. It will be soon, within the next two weeks or so.

Any other questions?

M: How does Giant Step Productions function within Leo Burnett? Do you have to sell your services to your clients or is it more of a function of when the account teams and planning, they might stop and think, "Oh, yeah, we should do something with interactive"? How is that working?

Adam Heneghan: It's actually really interesting, and we change our model about every week, just because the stuff changes so much. Within our group — we're part of a group called the Interactive Marketing Group at Leo Burnett. Some of you may have not heard of [Rashad Tobakawalla] who leads the group. He talks at a lot of these seminars and is thought of as a visionary in this stuff. And what he does, he sits with the lead teams on every client and any time they're discussing about next year's advertising or a certain campaign they're trying to do,

and we try to stay on top of what's going on within the agency — keeping in mind that if there's something there that we do that could help and provide a solution to that marketing objective.

So he stays on top of that kind of stuff, as well as we all keep our eyes and ears open and make everybody within the agency aware of what we're doing. But you also don't want to do that too much. You know, I heard earlier, the gentleman before us was talking about having these meetings where 30 people all of a sudden show up. Everybody wants to be involved because it's the new hot thing. And we like to call those the “thundering herds,” and it's just the kiss of death, everybody getting their finger in there. It just slows everything down. You know what it's like when everybody's in charge of it. So we try to [inaudible] to a few key people and people who are capable of making decisions, not people who have to go get permission somewhere. That's one of the ways.

We usually end up with a mainline creative and sort of a mainline account person that pushes these projects through.

M: [inaudible]

Adam Heneghan: The question was, how many people do we have working within our interactive creative group? And also, you wanted to know the length of time to create a site or some of these ads?

M: How often are you updating these sites?

Adam Heneghan: Okay, real quick; just as far as the updating goes, it depends what you mean by updating. As far as changing the whole look and feel of the site, obviously that doesn't happen very often, but small changes will be done immediately, and they happen daily.

We're adding new stuff to the areas, and we have deals with that [inaudible] we keep that in mind and the people on staff are constantly adding. Another interesting thing about this is you're introducing clients to a whole new medium — everybody's trying to figure out this whole new medium. New tools become available and the client's heard about this, or this has given me an idea to do this, and you have to be ready to keep adding those things and that's part of the Internet.

And now I'll try to answer your question about the creative people. In Giant Step alone, we only have five people doing all the production. And then we work with the traditional creatives, and usually they become guidance for us to be able to go to and make sure we're staying within brand.

M: [inaudible]

Adam Heneghan: How do we signal what?

M: [inaudible]

Adam Heneghan: Oh, for anybody going on there? We don't actually have any time limits. Anybody can go on as long as they want.

M: [inaudible]

Adam Heneghan: Everything we're doing right now — and one reason you don't see a lot of that up there right now is that we're trying to build it the smart way, as opposed to doing

something real quick like a flat file or something like that. We're trying to create everything so it's automated into those companies' networks right now, the way they're doing business.

So, as an example, at United, they have a press release. The normal route the press release takes before it gets out to being an actually printed piece — this will be one of the links in that way, so the press release will be typed in and it will automatically be updated on the server and go ahead and be printed at almost the same time, so everything should be timely.

We're trying to link into things like, for instance, reservations. The Apollo system is what we're working on right now, so that information probably already exists out there. For those companies that it doesn't exist, we're trying to encourage them to build systems that do offer that.

M: [inaudible]

Adam Heneghan: Usually it involves — right at the very beginning we have discussion. Are you saying like when the user comes on, is there a date stamp at the bottom? No, there isn't. And we're trying to get into a situation where there is never a situation where you'd have information that's outdated. And that's how we're setting the sites up to make sure that the information is timely. It doesn't make a lot of sense for United to be up there with information on their flights of last year, so we try to keep that up, so that it's not an issue.

M: I'd like to hear your thoughts on advertisers advertising on-line, advertising their Web sites using banners on other services. And if you were to give a recommendation to Oldsmobile, would you head up their Internet site, their Web site? What percent of the development cost should go towards the creative and maintenance and what percent should go towards promoting the site?

Adam Heneghan: I think that obviously that is a decision that would have to do with the media people, but definitely for certain things you're going to want to drive traffic to it and I'm not so sure people — it depends what the objective of your site is. If it's to get people excited about a product, like the Maytag thing, I think it makes more sense if someone's in the market for an appliance or going to go find it as opposed to putting a banner somewhere. For Oldsmobile it probably would make sense to have a banner somewhere and somewhere that gets a lot of traffic.

And, you know, those places right now are actually kind of clear-cut who to go to. You have your *Hot Wired*, you have your ESPN *SportsZone*, you have places like that, and there are some really well-done magazines like that right now that people are hitting for fun.

One of the ones that's the most interesting to me is *The Spot*. Have any of you seen that? It's kind of like a "Melrose Place" diary that's going on on-line, an MTV "Real World" kind of thing. And when we first discovered it we were scratching our heads, very skeptical I guess, being the Generation-Xers we are or whatever they call us. This was not real. And there's this whole diary going on with these six incredibly gorgeous people who live in this house in L.P., and have these incredible lives and you read their journal every day with these pictures of everybody they're meeting and hanging out with and sure enough, it turns out it's an ad agency in L.P. that's creating the site. And they've spent, I think, \$600,000 so far. It's only been up for about four months, but they're still trying to figure out how it is they're going to work advertising into it. They're getting everybody hooked first, so it's kind of interesting. I'm sure they'll add banners or something at some point.

M: Do you have any problems or have you had any problems that you've had to deal with the legal people at Burnett, like Carla, on advertising liquor on the Internet?

Adam Heneghan: Yeah. Dewar's is not on the Internet right now. But the name that he brings up is actually an interesting part of our group. The Interactive Marketing Group that I mentioned is made up of people with disciplines from across the agency. We have some media people, so they can give their guidance and advice from [inaudible] they come from, creatives and legal. And the legal person we deal with is [Carla Micolotti], who's second in command at Leo Burnett in the legal department, and she was actually one of the first people out there that went and met with Al Gore's people when nobody was addressing even advertiser's rights in this new world.

So many people are trying to — the government, too — trying to decide how this is all going to work, who's going to control it. And there are so many legal issues that come into it with copyright laws or even some of the things we mentioned earlier about things that are happening in foreign places.

In the case of, like, Philip Morris — who's one of our clients — and McDonald's, they had offices in other countries that were trying to do Web sites. And the problem is you have to make those people aware that when you're doing it in Amsterdam, you're also doing it in the United States. You know, it's going worldwide.

And so those are issues that I think everybody is trying to define right now. They're not defined yet, but she is in on those conversations constantly.

M: Totally different question: Is part of your charge to do anything in the way of training, either informal or formal, to the more traditional creative people in the agency, how to do this stuff?

Adam Heneghan: When we first got there, we did a lot of that. It's actually an interesting question. It's something we struggle with all the time. In some cases, I don't know if it's a best benefit to do that. You might take traditional people and now you have to... Part of the advantage we had is we had two years to really sit down with this stuff and play with it as toys, and we were fortunate enough to find somebody to give us the funding to go buy all this equipment and get good at using it. We had client projects here and there, but really, we were in [inaudible] City. That's where we started our company, so there was not much distraction. And we sat up there and holed up, learning how to use this stuff.

And that's one problem; we tried [inaudible]. I think a lot of them can pick up on it and everything, but as far as do you really want them in there trying to learn all these tools, is that the best money, or the best money spent on your creatives? Should they be doing that or should they be coming up more with the brand and the concepts and trying to understanding the medium overall, generally, to be able to assist you. I think that's probably the better answer.

Any other questions?

M: How do you get paid? Do you get paid by the hour? Do you get a retainer? How do you like it with a client to get paid? Do you make a commitment for six months or what?

Adam Heneghan: For the Internet? Well, I mean, some of those ones, like the CD-ROM stuff, what's interesting about that is once it's done and it's pressed, it's gone. And for that we work out how much time it's going to take. I don't know how the agency fees work. I can only speak from a production standpoint, or at least I'll plead ignorance to it. But basically we figure out how long it's going to take us from a production standpoint, as graphic designers and that kind of stuff, and figure out a fee for that and come within the price estimate.

Or in the case of the Internet or something like that, we have to figure out how much time they're going to have us keep updating, keeping it timely, adding things as the tools that are around. So for that we figure out a fee for how much it's going to cost per month to change that. And that's based on so many hours. Everything's based on hourly fees.

M: My last question is, do you think that the playing field has been leveled? Is there some advantage working doing your job at Leo Burnett or could you go around the corner and do it with Elite Partnership tomorrow and really achieve the same goals as you're achieving?

Eric Heneghan: It's an interesting question. What it leads to is an added benefit. I definitely do believe there's an added benefit to doing it with traditional creatives, traditional marketing minds, traditional media people. Everything with an agency, I definitely see the added benefit. The place where it causes concern is [where you ask] is that added benefit worth the difference in cost from going somewhere like, I don't know — Five Guys in a Loft, we'll call them. There's definitely a difference there. And then you have to judge what that value is, and I think what agencies need to do is realize this is also a different medium and maybe price some of that differently, to give people who aren't paid [inaudible].

Because you have such overhead. The whole model is set up to work with television and print, which is an entirely different model than this. So as far as the economics that come into it, actually the biggest issue is that I do think there's an added value and I think the reason the big agencies now have the big clients is that very reason. It really leveled the playing field, not only for interactive stuff but even the television, print — I mean, in the past, you used to have ungodly amounts of money and access to resources, be able to do post-production or anything like that, and computers have really leveled the playing field across the board for all mediums. And if you have a good idea, it's not that expensive to execute it anymore.

Andrew Jaffe: Adam?

Adam Heneghan: Well, the one thing I will say is that from a development standpoint, it certainly is. The Internet is much different at a cost point, I should say, to the client than is a CD-ROM development. The things that we've been sort of struggling with are not so much the programming, not so much the graphics we're creating, but it comes down to an issue of organization and of gathering all the information. That's really where most of our time is spent in developing a Web site. Lots of times in CD-ROM we'll be writing code or creating the images, things like that. So, it's sort of a different cost than it is, and it's a lot cheaper to do, even from a production standpoint, on the Internet. And that certainly has leveled the playing field. You really need a computer and a connection and then you're off and running.

They are converging, both those things. That's what's exciting about it.

Andrew Jaffe: Okay, folks. You've been a great audience, those of you who've stayed the route. We'll start tomorrow morning at 10:30 with G.M. O'Connell from Modem Media.

Adam and Eric, thank you very much for a wonderful, rich presentation.

If you are leaving tonight and not coming back tomorrow, please leave your evaluation forms with Matt Pollack, my associate there, who'll be at the door.

ADVERTISING FORUM
HOW DO YOU GET CONSUMERS TO REVISIT A SITE OVER AND OVER?
A CASE HISTORY: ZIMA CLEAR MALT BEVERAGE

MODERATOR
Andrew Jaffe
VP/Executive Editor, ADWEEK Magazines

SPEAKER
G.M. O'Connell
Partner, Modem Media

Andrew Jaffe: G.M. O'Connell got out of Middlebury College in Connecticut and decided to go skiing in Vermont, and then decided to go skiing in Aspen, and that is probably a central point to his going digital. So some of you may want to consider Aspen and skiing in your own training. At age 24, he joined CompuCard and was the product manager of the first electronic shopping mall.

In 1987 he decided to form Modem Media. In those days, as you know, digital media really didn't exist to any degree and a lot [of] his early days were [spent] trying to explain to companies what this would be and get them to fund pilot projects. Today, the company is billing about the level of a hundred million and it's got 85 employees. I think *Adweek*, in its articles, has considered it one of the two or three leading digital marketing communications companies in the United States. Its clients include AT&T, Delta, MasterCard and Coors, and we'll be discussing, among other things, the Zima site that Modem Media created for Coors.

There's a lot of call on G.M.'s time — he's got to run the company, he's got to take care of clients, and we're all fighting to get him to speak and train the rest of us, which he's been very generous in doing, he and his associates. With great pleasure, I present G.M. O'Connell.

G.M. O'Connell: Thank you very much, Andrew. It's great to be in Boston in October, and if you're a Red Sox fan, this October my heart goes out to you once again, and I promise I will not make any Bill Buckner jokes. It's great to say that as a Yankee fan.

I think the name of this Web, or the working title, I believe, of the presentation is, "How Do You Get People to Come Back to Your Web Site Time and Time Again?" I'm glad that you all came to this session today, and I hope that you will stay awake and stay awake and stay awake throughout this two hours of my being here. What I want to go through today is one of the attributes of the Worldwide Web and digital communication in general, and why do I as a marketer care. We've taken a look at some of the functionality of the Worldwide Web recently and there's still something that we as an agency are trying to get our hands on — certainly no one has all the answers, and we do not claim to, but we've started to break out the different attributes or functionalities that define how we use the Web as a communications tool in different zones.

I want to take you through those zones so you can better understand what we're attempting to do with the Zima brand, and I think we'll have a long period for Q&A at the end, right Andrew? The key mission... I don't know how many of you saw this in the *Sunday Times* last week, this gentleman's name is Lawrence M. Crowse, he's a physicist at [inaudible] & Reserve in Ohio, and his specialty is trying to figure out which *Star Trek* technology will actually come true.

And [inaudible] to go with Zima, he says if you look at the way bandwidth is exploding and computing power is exploding, by the year 2200 you will be able to actually do the transforming — transporter technology.

That's our idea of saying once digital communications really happens we will, working with this gentleman, be able to transport Zima electronically. But until we're able to do that, we've really got to focus on doing marketing on Zima, not delivering it.

Andrew did a great job talking about Modem. We were the first agency out there, and one of the biggest today. We don't just exclusively focus on digital or on World-Wide Web applications. In fact in Zima we used a lot of telephone voice response — and I have a big project going with AOL that I'm not going to talk about — but through the years we've been able to work with clients to do over 200 campaigns on six different platforms from voice up to virtual reality. What really matters, and I think that this is what many agencies and many marketing communication companies need to focus on as we leave this century, is designing and creating and managing interactive relationships between people and brands. And that's really what I'm here to talk about today.

I'm not really here to talk about Internet growth except to say that we have all probably been reading the press articles and it's "hockey stick [growth curves]." We'll come back to this as we explore Zima in some of the psychographics, but we're not as concerned on the Web right now about demographics as we are about psychographics. The typical user is an information seeker who will use his technology to better control and manage his time — as Dave talked about yesterday, and I think he is pretty dead on — they're early adopters and they're very much opinion leaders.

Technology has become something of a badge value [inaudible]. *Wired* magazine has identified as a visionary, and that's very true. Three years ago you were a geek; now everybody wants to use you to get themselves on the Internet. So if you fit in that category you are a mentor-in-waiting, and that's something that we really want to capitalize on. The people who use the Web, use the medium to really enhance their lives, as I mentioned, and they really [inaudible] as a transportation medium, as a way of really getting from one place to another, being able to go at a click from one place to another.

Now, why did we get involved? And why should any market really get involved? First of all you've got to look at the numbers. If you want to have relationships between brands and your customers, you got to go to where your customer is, and that may be on the Internet right now. More importantly, we try to create a place where a brand and the people can meet and provide a context for that, worlds for that, zones for that, as we'll see. Retention recall is much higher when you interact with messages and ways to save money — we'll see some of those.

What is it really all about? Well, it's really all about control and manipulation of digital files in real-time. That may be by the targeting, by the customer pulling those files, where they are in control of getting what they want in terms of information and entertainment, and the advertiser or marketer pushing and trying to anticipate the needs of the user and pushing files, which may be sound files, textural files, graphical files, video files — it doesn't matter, parts is parts, bytes are bytes.

When we can get a handle on this we begin to understand how to create innovative and very personalized communication. But more and more, this is really not about technology, and I'm sure as you're finding out, it's really about MIS guys becoming creative directors. Really what it's about is people. And it is really the WorldWide Web. It's really a new dial tone. It's an open system.

Anybody can connect and a lot of people are sort of chanting that mantra right now. But for me, when we decided that we were going to get Zima involved on the Web — it was actually before this time last year, when nobody else was really there — a few technology companies were there, and we started taking a look at how it was really being used by people, not by companies, and we came across this: I still love this; this is a birth announcement, the

first one I ever ran across, and there's a lot of those up there right now, but this one is by a guy called Brandon. That's his kid, that's his wife. Brandon is here in the audience. I never met this guy, but I'll get to meet him later. This is what it's all about, folks.

It's also about wacky things like UFO pages, and we showed this to the brand and we said, "We don't know exactly what this means, but we know that you can create a world that you get to control and the users can also participate in." This is the UFO Home Page, and I like this one, and this is one of the original ones — this thing has been up there for a long time — where you can click on any of these different links to get information about UFO sightings. Down here there's this U.S. law that forbids contact with aliens. How can you not click on that? I don't know if Newt Gingrich knows about this yet, but it's already been passed by Congress, which is why it's not in the Contract with America. Really importantly, here is that contact between U.S. citizens is illegal, but also their vehicles, it's strictly illegal. So, stay away from those illegally-parked flying saucers.

So this is the kind of world that we find and the attributes the Web has brought to the table. It can be summarized thusly: It allows us as viewers, if you want to call us this, to program and control our own individualized experiences. Sometimes we talk about the notion of mass individualism, where you can publish one document or video game. For example this, I would give everybody in this room a videogame, say *Sonic the Hedgehog*, and you'd play that and come back, but everybody would have a similar, but very individualized, experience. But if I gave everybody in the room a copy of *Apocalypse Now* and everybody went and watched that, you'd kind of have the same experience viewing that. When you're in control, you're creating your own individualized user experiences. That's a double-edged sword, and we'll talk about that.

Access and product information is getting quicker and easier, and therefore advertisers are more reliant on consumers to seek out advertising.

Now, the net affect of this can be either one that is very commoditizing — if all I want to do is get my product and my attributes out there and I've got a very high-premium brand, it would be very easy if that's all I do to commoditize my brand, sort of torpedo my own ship. Or, you can use these worlds and these zones to create loyalty; of course that's what we want to do. You've got to be very careful about how you go about it.

I think one of the keys are appeal. It's got to be very aesthetically appealing, it's got to be very easily navigated, very easily utilized by the viewer or the participant. It's also got to be extremely relevant, i.e. targeted. It's no big deal, I mean, all advertising has to have aesthetic appeal and has to be extremely relevant, but you can't ever forget that.

Most importantly, I think, is we've got to understand the unique attributes of open digital communication, and it's those that I want to talk about in terms of these zones. I'd love to get your feedback later on about this because this is not something we have. We're working on this on an on-going basis. What we begin to see at first is a point-to-point zone. It's sort of a service zone that a lot of people were talking about yesterday, which I think is maybe one step to what the Web is really all about — where you can do point-to-point transactions, you can chat or E-mail, or have customized point-to-point, sort of customer service, applications, or even digitally deliver your product, i.e. download a specific software browser something as a digital delivery of a product.

And that boils down to the Internet and the WorldWide Web as a communication medium, not as a publishing or broadcasting medium; that's really where the big... what is it... it's neither — it's somewhere in the middle that we haven't even defined yet.

For example, that can be some of the baseball news briefs that got keyed up here. Here's one, it kind of got corrupted a little bit, but people can go the *Netscape* news and they can talk about baseball. We went on and grabbed something about the World Series; people can go and talk about past baseball experiences, sort of point-to-point communications or a

form of communications. Here's the Sci-Fi channel. We did the UFO home page — I had to bring this in here — where you can write back and communicate on a one-to-one level with the Sci-Fi channel. We saw yesterday the Fed-Ex application, I believe everybody saw that, so I don't have to talk about that. You can go in and trace your package, real point-to-point communication.

The next thing I want to talk about is basically this programming as really a file server, or the Net as a broadcasting zone. Basically you create content and it becomes, from a marketer's perspective, a media play. I might want to associate my product with that content to point to it, or more likely I will go to that content and say, "You guys have such great content, I want to buy space on that content and I want you to link me or customers back to my site."

We think right now that this is a great way to use the Internet, as sort of a herding device, and I'm not sure that's all of it, to be quite honest. And an example of this is Time Warner's *Pathfinder*, or the CNN site, or what Dow Jones is doing — they're all sort of publishing applications.

Next I think is what companies will adapt for their own use, which I think is sort of standard info. These are the "Levitown Rowhouses" of the Internet right now, and there are thousands of them out there. There's EPIC, there's Talk to Us, there's product information, there's employment opportunities if you're a high-tech company, there's developer's corner, and to me it's sort of nameyourcompany.com. It's good, but that's only one zone, and it's very much "your company as publisher." And so the model done earlier is to link, to you create your standard zone, go out and buy space on the programming zone and break people into it. And that's sort of a model that a lot of companies are pursuing right now.

Novell is one of the better companies doing this right now. I'm not treating this site very fairly because I think it's a great site, but it is very much one of the standards, although better than most. One of the great things about it is that you can call out using form space navigation to [inaudible] product and [inaudible] the language and get the links to all the information in that language, which is a great... you should go in and check it out, it's really well-done. You can see here what's new. *CyberShow* is actually pretty good, with technical information, product sales, the employment opportunities and developers are on there somewhere on the right side, developers' services.

The last two zones are what we have to pay attention to because this is where the Web begins to become a new type of communications medium that doesn't exist anywhere else. Each one of these previous zones is really borrowed from another model — from broadcasting, almost a telephone communications type of a model.

The next zone is experiential, where there's an extremely high "wild" factor. You start to see new forms of communication, and you see the users in some sort of remote, voyeuristic control. We talked about the Internet before, the WorldWide Web as a transportation device. Well, we start to see it here as a transport for raw materials, maybe not Zima or people like in *Star Trek*, but things like — and we'll get to "the amazing fish cam" in a second because I think it is the most used example of that. Has anybody gone to — this site is beginning to get popular — the teller robotic garden? Anybody at all been there? Four people. Not enough. Everybody should go check out this site, it's very interesting.

You control a robot over the Internet that plants seeds, waters, and after that the plants grow. It's basically a robot in the middle of a bunch of dirt, and around that there are seeds and water and different implements that you can basically tend a garden with. The whole WorldWide Web community can go in there and basically see this garden, and so you're creating a very interesting experience, where you are going to that garden and actually doing things remotely. It's very interesting.

The “amazing fish cam.” I get to go in front of the guy with the fish tank. Intel’s got a great use of this sort of zone, where you can go out and sample their new microprocessor. So if you can get into this, it is tremendous. If anybody is in the room from Intel, we need more bandwidth here. You can go in and basically try it out and render an object in real-time utilizing their equipment. So you basically go in and create something utilizing their product. Then you get to look at it. This is a fantastic sampling device using that experiential zone, where I can experience the product as I can get to a place.

The last — and I think where a lot of work will be done very soon — is this collaborative zone, where we’re able to basically create shared tools that unite people in some sort of common experience in which we allow people to influence content based on those tools that are provided to them. We’ll see an example of how we’re using that with Zima. People will collaborate or potentially compute, do different things, using the Internet as a unifying network.

A good example of that outside of the Internet right now is AT&T’s Imagination Network, where I can give everybody a golf game, a tool, and I can play golf against Andrew. I might be playing in Boston, Andrew might be in New York, and we each have the same tool, and I can look at his shots, and he can look at mine and a scoreboard keeps track. Or just utilizing the Network as a way of linking our experiences and we’re collaborating in a game of golf — The Riddler is kind of like that. I don’t know if anybody is using the Riddler site, where basically you’ve got a whole bunch of people competing to find links in different sites or find icons in different sites. It’s not a great example of what I’m talking about but at 7:30 this morning, it’s the best. I’m just kidding.

What does this all really boil down to? I think the *Economist* said it best. There’s a survey — if anybody wants this, I’d be more than happy to send it to you — I think it’s the best writing that’s been done on the Internet anywhere in a general interest publication. On July 1 there was a survey on the Internet, and one of the quotes that I pulled out if it was, “The Internet was... people realize the Internet was just not a way to send e-mail, it could be a place to visit full of people and ideas. The growth of the Net is not fluke or fad, but it is the consequence of unleashing the power of individual creativity.” And that is really what the Web is all about, and that is damn frightening to us as marketers, where we’re not used to utilizing our customer’s creativity to rally around our brand. That, folks, is exactly what we’ve got to do and therefore our experiential collaborative zone I think is exactly the way for us to do that.

The only problem is that we started coming to all those realizations about eight months after the first Zima site was first done. What I’m going to show you is the way Zima has worked. Then at the end I’m going to tell you to forget everything you’ve seen because it’s going to be a lot different next year. I can’t give too much away, but I’ll take you through how the whole thing came to be and what’s there. Who here has read about it, who here has read about the Zima stuff? Who has actually gone there?

Wow, well, thank you very much. Anybody who wants a Zima, drinks are on me, after lunch. Here’s the site. What I’m going to try to do is toggle back and forth. This might get a little ugly, but I’ve got a... well, you’ll see. This is a Home Page, and we’ll come back to that in a second.

What is Zima all about? Well, it’s a clear malt beverage and it was born out of a lot of research that Coors Brewing company had done in the early 90s. Survey test after test on consumers showed they were demanding a lighter, more refreshing alternative beverage to beer or mixed drinks or wine coolers, and that’s really the need that Zima came out of, very much a user need. Regional testing occurred in ‘93 and ‘94 and national roll-out basically happened a year or so ago. Zima.com was a part of a national roll-out, and there’s both a voice response component and an Internet- based component.

The original site, which I'm not even going to show you, was there for about six weeks, and we said, "This is really horrible," and we came up with something else. But on September 15, it was the first consumer-packaged good to put a product, really, on the WorldWide Web. Coors Brewing was the first brewer on the Internet, the first consumer product to put an Internet address on the label. There's both an Internet address and an 800 number on the bottleneck of Zima. One of the things that we want to do is try to position the company in front of the consumer as a leader and an innovator as something — and we'll get into this — sort "on the emerge."

Our objectives were to reach primarily males between 20 and 34, to think about the matching facts to the Web audience here, associate Zima with things that were on the emerge, and whether there are emerging technologies, emerging sports — there's a lot of extreme sport sponsorship of Zima this past year — different emerging music and so forth, and things that were on the emerge. We wanted to link to things that were different, changing, fresh, and new. We wanted to be able to create a feedback loop with consumers, build a database and a foundation for a relationship-marketing program. We wanted to generate a lot of press attention, and I think we're pretty successful both in terms of trade, and much more importantly, in consumer press and broadcast. We wanted to tie what we could do on the Internet and what we could do on the telephone to actual purchase when possible.

Our creativity was really to try to build a world for the brand and its users, its customers. We wanted to capitalize on the badge value of emerging technology, especially — and really exclusively — the WorldWide Web. A lot of what we were able to do with Coors is built on trust and faith. We went in and we were able to convince them of the brand; and for the agency folks, we were very fortunate because a lot of it was done on faith. Nobody knew how quickly the Web was going to explode and grow. We said it's going to happen, and they believed in that, and that's exactly what happened. So we're very lucky and very fortunate there. But it's not enough.

We talk about people coming back to the site. You know, "How do I get people to come to the site?" What we've really strived to do is not herd people into the site so much, and in concert with that, really distribute the site to the rest of the world. That is another way of looking at it, and we'll get into that in a little bit.

We wanted to leverage the attributes of the WorldWide Web by capitalizing on some of those zones that we kind of knew existed but haven't really thought about too much a year ago. The tone we wanted was one that was very useful and very much in charge, in control. Very quickly, the mechanics were really to add value for customers in every stage of their brand adaption, adoption life cycle — from awareness all the way through loyalty and advocacy. If you look at the media side, the flip side of that distribution model is that we did want to herd people, and we came up, everybody got excited about the notion of herding, trapping and domesticating, and the way that we tried to do that was to publicize the site, both in terms of paid publicity or links and free attention.

Once we had people coming to the site, we wanted to engage them in relevant, compelling content. We wanted, above all, to initiate a dialogue and set the stage for action and, hopefully, the action would be purchase. That would be loyalty, and that would be mentoring or advocacy. As I said before, there are three areas we went into.

[One is] voice response — and I'm not going to show the AOL. Zima on AOL is very interesting. There are a lot of things we can do on AOL that we can't do on the Web right now, and if we've got time at the end, we might want to talk about that.

We'll focus here on zima.com. So here it is, again, and the first thing I want to show you or talk about is that one of the things we wanted to do to keep people coming back was to get them involved in something that happened in an episodic way or serial way. We came up, after

a little bit of searching, with something that really struck a chord with our constituency and those are the Duncan Chronicles, really just called "Duncan." Duncan is a 20-something guy who's got a good job in some sort of high-tech business, you're not quite sure what it is, and he has friends that you've been introduced to throughout the year. He's got a love interest, Alexandra, which has been an area that we've really focused on lately, the one that's really struck a chord with some of our users, or most of our users.

What we try to do is just provide this biweekly journal with Duncan around. We elicit or we provide occasions for purchasing Zima throughout this episodic adventure and we wanted to develop a very easy, quick, easy-to-read format for doing this, sort of iambic pentameter for the Web. If you think about it, nobody wants to read a screen; I mean, I hate to read a computer screen. Everybody in this room hates to read a computer screen. So what we needed to do is create a multimedia format, although highly restricted by the bandwidth of the Web.

Each story features an image at the top, an icon that you can download. We talked about distributing a site [so that you] can download that icon to launch applications on your desktop, a sound file and then a pointer. We don't believe in keeping people in this site, but pointing to other things that might be relevant to their lives and helping them control things better, [so we provided] a pointer to an external site on the Web. We made that a big part of it. We don't want to have people come in a site and keep them there and pummel them to death.

What I'm going to try to do here is just go off to it... Here is, this is an episode called "The Kiss," where Duncan first kisses Alexandra, so it's entitled "The Kiss," and we can read along here if you can.

I'm not going to attempt to read through this, but essentially they go back to her place. She's got a dog. [She says,] "Duncan, I had a wonderful time." Duncan, in a wonderful pool of clichés, immediately evaporates [inaudible]. They swing the door open, and if I download that sound, real audio is coming soon. I don't know if anybody can hear that. Could everybody hear that? There's a swinging door that opens, and you can download that sound and use that maybe when you shut your computer down or open your computer. She fumbles for the key, and here's a Zima-branded key that you might use as a button on your desktop. You can download it somewhere else. And then Snyder the dog comes. This dog has been driving Duncan crazy because every time he tries [to be] intimate with Alexandra, the damn Snyder gets in the way. But not tonight, and eventually Snyder falls asleep at the door. If I click on the door, it'll link me to another door, another site out onto the Net, but I can't recall exactly which one.

So those Duncan episodes continue on every week. Here's one that's up right now that's Halloween based.

(Let me go back to the top.)

They go to a costume party and they don't win the prize. I urge you all to go out and see it. Basically, the hook here is that people keep coming back for the Duncan episodes every two weeks, and it's working. The next area that I wanted to go into, if we can go back, is the "fridge."

The question that comes is, "OK, we create all of this stuff every week, now where do we keep the good stuff?"

Well, you keep the good stuff and the cool stuff in the refrigerator, so we came up with the fridge, and that is our repository for all of these great digital goodies and other content that we want to distribute out on the Web, [and it's] a spot where people can come to get them. We're going to go through the items on the right first. There's the fridge, and the items on the right were all downloadable multimedia files that are accessible through the fridge. There are views of a lot of product imagery, small sound files found in Duncan stories and other places,

icons that came out of Duncan stories and some other places, that are all sort of Zima brands, both through the Macintosh and Windows.

What we're trying to do here is provide a lot of value [inaudible] and diversions, but where the real hit is that we've manufactured little infomercials or video games that people can play that are brand-centered, and they can exchange notes about how they play or even collaborate on how they play using the Net as an experimental zone, a collaborative zone. We'll see a couple of examples of that. We'll go into the fridge. Creak — another sound file here — and of course, here it is.

It's an image map right now, and you open it up. We'll talk about the freezer, where only the really cool people get to go, in a second. Then there are leftover Duncan episodes. We'll go into views and icons and a few others. I got some bookmarks — a quicker way to go. The views that have been in the site we use to tell a little story in which product imagery is utilized, and basically people who are loyal Zima drinkers would definitely download these files. We've had people turn them into screen-savers. We talked a little bit before about unleashing creativity. When you go into this kind of mode, you are allowing people to take your brand access and do things with them. And that's going to happen anyway.

Here we've had people come back and utilize some of these images in screen savers and other things, which has been absolutely great. There's a little story here, but you can see all of the brand imagery that we use. So you can go back and just download all of this interesting stuff. This is really the popular one, sort of a Stonehenge Zima. You can't really see that up there, but these are refrigerators, and this is a Zima bottle with a full moon. So that was one that people liked a lot. Now a lot of this we did at the beginning, and I'm not sure we're going to pursue this too much in '96. [We asked,] "What are people going to use" And we took a lot of stuff and put it into the site, we thought very strategically. But by the time we were done this year, there was five and a half hours worth of stuff that you can do in the site, which is way, way too much in our opinion. We'll get back to that in a second.

So that's views. If we go into earwax, these are all the sounds that got loaded in... [playing sounds]... This came out of the date, [playing sounds]... oh, no, excuse me, that was when Snyder licked Duncan's head when he was on the couch and woke him up. We don't advocate those kinds of dates. This is another one from a baseball Duncan episode, where he went out to the company softball game and he was sort of Casey at the bat. [plays sound] Well, I got that one wrong, too. That was another Duncan episode.

Icons are all of the different icons that you can bring in either Mac or Windows format onto your desktop to utilize. You see, I don't know how well you can see them, [but it's] all Zima branded. There's a baseball, there's a Zima phone, there's a Zima perfume dispenser, there's an AOL logo, [from] when we did a press promotion with AOL. There are some other icons you can bring down to utilize. We found that, [with] the Net here, many of our users spend more time in front of their computer screens than they do in front of the television, and if we can brand the computer screen with some sort of a Zima brand element, so much the better. That's really what we're trying to achieve here from a marketing perspective.

The last area is diversion. There's one game that we worked with the developer to create, this little infomercial. We'll play caption contest in a second. My favorite game is a game... remember *Asteroids*? We developed a game like *Asteroids* that you can download in about a half an hour and basically you've got this little Zima bottle and it can shoot at all these bottle caps that come up through and break up into smaller bottle caps. It's like *Asteroids*, but every game element is Zima branded, and people download that and play it a lot. We've had very many—thousands and thousands—of downloads of that game. Let's go back to [the] presentation. So those are [examples of] how we try to distribute content out of the Web, and

we don't necessarily have to have people coming back to the site as long as we can take pieces of the site and get it out onto people's desktops.

The next area I want to talk a little bit about, and this happened so much faster than I thought it would, and people realize it's the essence of the Web and the most basic element of the Web, I guess: pointing and hyperlinking. If you are what you eat, well, on the Internet, you are what you point to. That is from an individual basis. I'm doing a lot of people's Home Pages out there just to collect people's link to their favorite things. As a brand, you kind of have to do the same thing. We basically [give] consumers an idea [of] other compelling sites on the Web, and that breaks down into two main areas: One is all the places that Duncan goes to or where the last Duncan episode links to, and the other is one that's gotten a lot of attention and has been named in a lot of reviews, "The best bar and restaurant guide on the Internet."

We just wanted to tell people where they could probably find a Zima, and so there is this Zima bar and restaurant guide that's kind of buried in the site right now, which is a bad thing, but essentially it's a directory of directories. I can take us there pretty quickly. So you can see you've got Duncan's favorites. Those are all the different places he went to: a college, Seattle, London, he went and bought something for Alexandria from the Internet shopping network, fun stuff like that. Here's the Zima Bar and Restaurant Guide — bar-hopping in Buckhead. You know [that] you can click there and go to Atlanta, and then everything else is organized by location. There are all these bar and restaurant guides in New York City; Long Island; Troy, New York. Any place there's a bar and restaurant guide, we link to.

The last item I want to talk about is some of the relationships—marketing campaigns that we've done. Internet marketing should not, cannot, can never be just a World-Wide Web site. There is a lot more to it than that, and what we've done is we've focused on two areas, which [comprise] the relationships. Everything I've shown you so far is to get people to come spend a little time. But how do you extend that relationship? And you've got to be very proactive about it. You just can't put banners out there and every time somebody comes across it they'll say, "Well, maybe I'll go to Zima today." We can reach out on an individualized basis to everybody who's ever come into the Zima site. There are a couple of ways to do that. You talk about the old 70s saying, "If you really love something, set it free," well, you know, and then you've got to use e-mail to stay in touch. And if you're talking about setting people free to link out to the rest of the Net, well, we really do encourage that. We don't say, "Come to the Zima site and we're going to keep you there for as long as we can."

If we can keep you there for forty-five seconds or two minutes, that's fantastic. We don't expect people to stay for hours, which people can do if they want to. It just so happens that the average session is about five minutes in Zima, but that's way beyond what we really ever thought we could achieve. What's more important to us is to be able to stay in touch through e-mail. If you come to the Zima site, and you have any type of question, there's a section at the top, write to us, we will send back an immediate acknowledgment of your message, and we'll thank you for your feedback. Every single e-mail that comes in is individually read by a Zima customer service person. If necessary, if it's just a compliment letter, we'll say thank you very much the first time around. It might need some follow-up—it really depends on a case-by-case basis. But if a second response is really necessary, a more personal correspondence is sent out.

Step one is to provide some instant gratification: acknowledge and thank the consumer for their interest. Outline what you're going to do for them and you'll see the expectations in terms of what your response is [going to be], and basically acknowledge the fact that they've initiated the relationship and try to create, even on your first e-mail back, a bond with them. As you can all read (I apologize for this), this is a general response that you get back from Zima when you go in. It says, "Thank you very much for mailing to You Can At Zima.Com," (which is

the label on the address, which was a thanks for that). There's also a file that will be attached that would contain those digital goodies.

The next step is to make your communications relevant, especially following up with any questions they might have. Here's a letter that came in from this guy, Thor, and it says... this is a great one, almost chosen at random, not quite, but seriously, this is what Thor had to say, seriously... this is a joke, right: "I've asked around and nobody, I mean nobody, has ever tried a Zima. Who the hell is Zima? What the hell kind of name is Zima anyway? Some kind of kinky, Aztec virgin wacko deal?" There's even a Michael Jackson joke... "I bet Michael Jackson is behind the whole thing. Go ahead, you can tell me, Zima is a hoax, right? Go ahead tell me, I won't squeal."

We wrote back, we say, "Hey, hey, hey, Thor." No, seriously all comments are welcome here, no matter how scathing. He says, "I don't think you'll ever write back to us." And we said, "You're intimately familiar with Zima to leave such an original, comical response. Honestly, I got a good chuckle out of your message." Then we answer any questions that you might really have had about Zima, and we say thanks for the e-mail. We attached a file, [and ended with] "I'm sure we'll hear back from you if I missed anything. By the way, I won't touch your Michael Jackson comment even with your keyboard."

And that is from the Tribe Master, and we'll get into what the tribes are about in a second. And all of a sudden Thor wrote back, "Yes, I sent it in as a joke, but I'm truly impressed that you sent a response. That kind of response is very refreshing coming from a big company. I'm having a big-ass Halloween party. The ice tubs will be stocked with Zima in honor of your wonderful response. You are invited." And of course we wrote back, "Thanks, if that party is within fifty miles of Denver, I'll be there. If not, fill me in on the gory details. Heck, I'll even bring some complimentary Zima." The Tribe Master.

So there you have it. It's very difficult to do that, but we've been able to do it, and we've really gone in and tried to build, and part of this program is to try to build, a loyal core of Zima drinkers. With Zima products, like most products, really the 80/20 rule is at play. For Zima, it's more exaggerated than that. The last step in creating bonding and advocacy is this loyalty club that we entitled, "Tribe Z." And that's where we really try to integrate the customer into the company. We try to give them a stake in the business, build a perception of value with an addition of added value for them. We came up with this strategy that focuses [on the fact that] only the really, really cool people get to go in the freezer. And in the freezer, we wanted people to be able to, basically... we'll get back to that.

We wanted to be able to get people to create their own space and experience their own space. The first thing when you click on that freezer button, and I'll go back to the Home Page, we love this, we're thinking about, what kind of initial interface should we have, and sometimes it's hard to tell what you can do on an interface. So we made what we think is the world's biggest button. Now what are you going to do with that? Of course you're going to click on it. And then you're in the freezer, and as it turns out the freezer is really a loft space, and you can see over here there's a refreshing sign that can go on and off. If you click on this picture window, it can reload the graph and it'll be a newly generated picture that happens in the frame here. Actually the copy spells it out a little better than I can. If you click on the light bulb, it's a deep-thought generator and it kind of comes up with funny sayings. Click on the picture. It's a random image generator. Click on the fire escape. It's a random jump station that sends you out onto different places on the Web. So boom, you're out of the freezer all over. Then click on the wall, and it still does nothing, and that's our favorite. And you can see, it's a very sort of smart-wise... we really don't try to be didactic to people within the site. We really try to... people will try to catch on to what we do... it's very Web-savvy.

We also like to decorate the Web. One of the first things that all the people who belong to Tribe Z got to do was to decorate that [inaudible] space. The first couple of weeks, we took a poll on what color people wanted the walls to be. There were three [choices] up there and you clicked on one. Before we did that, people got to select what the Tribe Z logo would be. There was one of five different selections they could have made. That one won by several hundred votes, and some tight polling. And then we needed to have a plant in [the] space. You could decide which plant you wanted to vote for to occupy space in the Tribe Z loft — a cactus, a spotted fern, the turtle fern, and as you can see here, the cactus was the winner.

So that's Tribe Z. Basically, what people can do within the clubhouse is participate in its design, and there's a form there for communications. We use that whole point-of-communications zone of the Web, a combination of that experience and collaboration, within the Tribe Z location. And then finally, we do on-going mailings to the Tribe Z membership base. There's the latest one that went out. "Grab a rake and get out in the yard, it's autumn. According to most sources, autumn begins about September 23 in the United States. In fact, the season known as autumn or fall can start on September 21 or 22 or 23. The numerous oscillations and wild motions that the earth undergoes both in its daily rotation on its axis and its annual elliptical course around the sun cause the day of the autumn equinox to vary slightly each year."

We go on into this whole kind of ridiculous tongue-in-cheek explanation of autumn. We talk about Zima at the end and we sign it off, "Now that you know that, go chop some wood." We usually give people an ability [to respond]. We either attach a file or request some sort of response, but on this one we didn't happen to do it. When we do allow people to respond, we get over 90% response to the Tribe Z mailings. We also give people the opportunity to get their name off the list and every time that goes out, it's far under one percent.

So, people, to be part of Tribe Z, do want to become part of the brand. They want to inhabit that space, that world that we've been able to create. But we always give them the opportunity to get out and we don't invade their privacy. A couple of things that we're doing in the fourth quarter of '95 is that we're going to include a couple of promotions and a drive to each program. We'll talk a little bit about that. First I wanted to show you folks, if I can get to it, this multimedia game that you can download called, Caption Contest. This is one of the games that you can download from the diversions section. The whole idea was to center people back into the brand and allow them to interact basically with the television commercials that were running at the time. If you can recall: those black and white television commercials with no voice-over, just music running underneath them, people...and when you see the images, you'll recall the spot.

So here it is, Caption Contest. [sounds] If you read that, you can see basically how it works. It says click on... these are the instructions that occur... and this is a scene taken from one of the commercials. So if I go into the intro, I can start to play by understanding it, by seeing what people are doing. "Did I step into what I thought I just stepped in? Guys, why are we following this dog? I could smoke these guys if I wanted with the gentleman on the bicycle, life after training wheels, not so bad after all. Bring in ultra-hip 20-somethings. He's not having to use both hands, he's carrying a bag of Zima over there." This is my favorite, as much as it is painfully obvious. This is known as product placement. "Hey buddy, listen closely, please don't drop me."

You can play around with that a little bit and get involved in the brand, just download this off the Zima site. But what this game is really focused on is allowing people to enter a contest where they would basically put the words in the mouths of the people in the television commercials and then we would allow everybody a look at everybody [else's] response themselves...and just download the instruction set that would upload the... download what

people... let me stop for a second. We wanted to use the Web here as that unifying Network I was talking about before, so we gave everybody the same tools. [sounds], I can select shots from three different television commercials. I can create [sounds and other] things, different funny scenes, whatever people might be saying or thinking, so I've got walking balloons and talking balloons here. Then I can click on save and I can save it as a file, and then I can e-mail it to the Tribe Master. There's a contest going on and has been going on for a while where we're selecting what we think are the funniest ones out there.

You can also download... the only thing that gets sent up is basically an edit decision list on where the file resides or where each thought balloon resides on the screen and what text is in it, so it takes about five or ten seconds to download these 'thought' balloons and then you basically inject them into your picture. And you can see what everybody else is doing, allowing people to communicate with each other in a new way. That's Caption Contest, and we can talk a little bit about that later as well.

The last area that we've got right now that's tied to media and getting people to revisit the site as a Web, we're calling a Web Master sweepstakes. We're allowing people to go into the site and register as Web Masters [in order] to get a link out of a banner farm that connects them to [our] site. Then we will randomly select people who link back from their page into the Zima site, and if we randomly select one of the links that comes from their page as a winner, the Web Master is therefore rewarded. It's not a sweepstakes for the audience. It's really a sweepstakes for the media providers. Instead of us having to go out and try to figure out where we want links to be, we can go out and allow people to link in and just approve them, which is starting to work pretty well.

There's the Caption Contest and Web Master sweepstakes. I want to talk real briefly about the media aspects, because that is one of the things that will get people to come back. The idea is to drive traffic to zima.com and AOL, drive the frequency of interactions, and really drive depth of interactions. One of the things that we found is that it really doesn't make sense to link people to your Home Page, but to link them deeper into the site. There are basically four ways to do it: Paid pointers, we spent a lot of media money this year, most of it very well, some of which didn't work out the way we thought it would, or wanted it to; reciprocal voluntary pointers, which is sort of what [the] Web Master contest is all about; Web directory, register your [inaudible] wherever you can; and traditional media channels and packaging, whether that's [on the] bottle, whether that's every print ad for Zima tagged with the Zima URL, for example. How do we evaluate our media and our program? First of all, is the content relevancy Zima demographic, sort of IOL, verifiable traffic that the sponsor site generated? We need to know from our media providers. We need to see hard numbers.

We also, and this is going to be especially true in '96, we try to take a unique view on how the [inaudible] and positioning can work, and we're working with several media companies right now to test new ways of thinking about how banners work. The overall point here is that properties have to deliver a demographic and psychographic profile that is consistent with our objectives. No big news there. Some of the placements that we've done this year, I'm not going to comment on any of them, but you can see them all up here. Most of them I think you folks are familiar with. These are just a selection of [inaudible] two or three times as much this year.

Other media tactics we talked about: directory listings, generally free. Publicize the URL: We've got hats, t-shirts, etc. out there with the URL on them. (I did sneak in a couple of slides.) I'm not going to talk about AOL, but we can do things on AOL that we can't do on the Web and we're learning a lot right now. AOL, by the way, is very expensive and it can be difficult to work with an on-line service because whatever you want to do, you can't necessarily do. In a lot of cases, they've got to approve it, they've got to run it, so it's not open and there's a lot of

bottlenecks there. But one of the things we can do better on AOL is chat, and we're going to have a lot of chat interactions going on this fall.

The other thing we do is we use the Web as a research vehicle. We have done an intense amount of research to see if our investments are paying off. One of the things we've done a lot of, as well, is a lot of qualitative research with people who are in [inaudible] to find out if we are hitting the mark, and that's very, very important. You just can't look at click streams and say, "Well people are clicking on this stuff, so it must work." You really have to go back to qualitative. Some of that can be done electronically, some of it is done in person.

How do we measure results? You measure it in both the depth and the frequency of interactions, not just hit rates, and I think we all know that the number of hits can be very misleading. We've done a lot of demographic, attitudinal, and volumetric follow-up studies. We talked about the focus group surveys, etc., very much trying to determine right now the lifetime value of Zima loyalty, of Zima users and what their loyalty is when we communicate with them on an on-going basis over Zima.com. We're constantly redefining and redeploying. Has everybody stayed awake? Terrific, I'm glad to hear it. Results: seven-figure, in depth sessions is basically what we've seen.

We've had a hell of a lot of people coming through the Zima site. We've had a hell of a lot of frequency and a very considerable amount of reach—probably about the reach that we expected with more frequency, if you want to look at it that way. That's not really the way we look at it, however, but I don't want to get into some unique measurement, the way we measure it in depth. One of the gratifying things is that every week we're seeing double from the get-go. There was actually a little bit of a slow-down over the summer, which is normal [inaudible] for on-line services. But this double-digit increase is every single week. You can imagine how that sort of compounds out. We talked about over 90[%] response rate to [inaudible] mailings, over 23 million press impressions, which has really paid for the program in and of itself. We really hit that one dead-on in terms of if you go back to what our initial objectives were, and we've been able to establish that emerg[ing] position with the consumer and with the trade. Especially with the trade and getting the product out on the floor, the Internet program worked extremely well.

What are we going to see in '96? We're going to have Zima 2.0. We'll be using Netscape 2.0 as well. We already have the foundation for '96 executions in place right now, and if nothing else, what we were able to do in '95 was to get to a level of understanding that, hey, this works, number one, and hey, we built the tools and the foundation to really build upon that. We think we've established a lead that we couldn't play catch-up on—it would be much, much more difficult to play catch-up. Our goal is to leverage those zones that we talked about up front much better than we have been able to do in '95 and invite and encourage interaction either through participation with content or via dialogue, which was up [in] front of all the rest of it. I basically went through those.

What we ultimately, I think, accomplished here was to deliver customized content according to [the] individual's and/or group's previous interactions with the brand, and current actions with the brand. We created a context to receive comments and to receive the customer into the brand and allowed different customers to relate to each other around the context of the brand. Every targeted message in '96 will be measurable for full budgetary accountability. We still will not get to this level in '96, much to my chagrin, but the good news is it's become a fixture in all of Zima's marketing plans. The brand will continue to invest in creating the best interactive-interface-content-relationship marketing programs for the Zima consumer. Thank you very much.

Andrew Jaffe: That was great, and I'm sure all of us have a lot of questions. I know I do. Let me just warm up while we get the lights on, and we'll get Matt down front so we can start scoping out which of you have questions. G.M., it seems to me you've become a publisher, and it goes to my point yesterday that I think some advertisers are ahead of the traditional media in learning how to use the Internet.

Are any other advertisers wanting to be on your site as a publisher? Have you thought of taking Tribe Z and developing a hard copy, some kind of publication in relation to it? Have you thought of events? Has MTV come to you and asked you if you can combine with them? If you can just address one or two of these points. On the downside, is there a problem in a beer company becoming a publisher in today's universe, where we're so worried about kids drinking and spirits getting too much of our culture?

G.M. O'Connell: Yes, well I think they're all very good questions. Let me address the last one first. You're faced with an alcohol beverage company and the one big issue is minors. There are basically a couple of issues. One is anybody who joins [inaudible] today, needs to be 21 years old, and we do our best to verify that. There are ways around that, like there are in any other venue. There are "Drink Responsibly" signs all over, if you guys wanted to see one: 21 means 21 and it's right on the banner, and we address those issues straight up-front.

One question was, do we have plans to sort of pligh it out to any other media, and there's been some discussion about the Duncan episodes going out to traditional. But everything is defined and designed to work on the Net, so trying to sort of do a reverse shovelware, if you will, doesn't really make a lot of sense to us.

Andrew Jaffe: We'll keep those in mind. Let's see if the audience here has some questions.

M: How many people do you have on staff answering the e-mail?

G.M. O'Connell: Originally, we had... I guess at Topo, that's going back... that was done internally at Modem. About six months ago we trained the folks at Coor's Brewing Company's customer service center to handle the mail. They kind of duplexed back and forth—they're very good at multi-tasking between the voice and written communications, so that if they're not on the phone, they're answering e-mail. There's no real dedication just to doing e-mail. Their CRL staff, I think, is in the tens. It's not over one hundred, but it's probably between fifteen and twenty.

M: I have two questions. What do you know about cigarette advertising on the Internet and how does a marketing director or brand manager ascribe sales to this particular medium... or sales results, to this particular medium?

G.M. O'Connell: In terms of cigarette advertising, I don't think the cigarette companies are going to touch this. I'm not in a position to make a comment on that; we don't have relationships with tobacco companies. In terms of how you get it back to sales, there's going to be a lot of promotional things, I can't go into any depth or detail [about what] we'll be doing in '96, [but] we know that [it] will be basically tied to product purchase specifically. As with any promotion, you can tie the card back. In terms of general image advertising, you do some volumetric studies, you do some qualitative and quantitative research on the back end, but it can be difficult, just like it is in traditional advertising. So, there isn't a great way of knowing right now when you're looking at landing on the Net.

M: GM, you had an interesting point up there. You said give them a stake in the business. Can you define that a little bit more, giving consumers a stake in the business on the Page?

G.M. O'Connell: What we want people to be able to do is [have] a stake in how the product is, and we take their comments seriously in terms of any questions they have about product attributes. There was a product extension called Zima Gold that went out this summer, and we got immediate feedback from Zima consumers [inaudible] on the Web as to how they liked that product. That product is no longer being sold, so it can work to your advantage or disadvantage. [What? It seemed like the feedback was advantageous] but it, [the feedback], really helped us very quickly.

The other stake is in market[ing]. If you look on the marketing side, if you look at what we did with Tribe Z — painting the walls, [inaudible] what we think the logo's going to be all about. The logo will show up in print in the mail and it was basically the users who decided what logo we would use. It wasn't a brand manager [inaudible] sitting in a cubicle somewhere.

M: Have you done any work on your response demographics, not just your target demographics, but who's actually working at this thing and [inaudible]. The other question is kind of related to that. I know you're doing a good job in making sure that there's a 21-and-over kind of target, but how many of your respondents are under 21 and is that a way [that] you're establishing the product for under 21 people in the realistic part of branding?

G.M. O'Connell: I'm not sure I really understood the second part of the question, but let me go after the first part first, the demographic question. We do a lot of traditional data base overlays given the responses that we get back vis-a-vis what any database marketer will do. We also do more lifestyle types of overlays and have done some work with Simmons and some other big research firms. For example, we can see that a much higher percentage of the Zima audience in general, and Zima users in general, utilize on-line communications in the World-Wide Web than the general population. Those people that come into our site, whose names we collect when we go back again are pretty much the typical World-Wide Web users that have come in sort of outside the educational arena, the post-grad arena.

M: I would imagine this is kind of like cigarettes, you're actually branding and your loyalty starts when you're a teenager, not when you're 21.

G.M. O'Connell: Absolutely not.

M: How many people are involved in maintaining the Web site and how much does it cost and does it pay for itself?

G.M. O'Connell: The answer is yes, going backwards, yes. Saying the exact number of people that are involved is very difficult to answer because there are people at the agency, there are people on the brand side, there are people where the site is actually hosted. But I would say that it was about six to eight people, if you rounded them all up. Sometimes that's higher when we're in a peak sort of creative mode, and sometimes it's lower when you're in more of a maintenance mode. How much does it cost? I can't comment on that.

M: Two things: Could you comment on the initial development time to get this thing out of the gate, and second, the developmental infrastructure. We do a lot of [inaudible] consulting and

Web sites [inaudible] working. Have you done staging servers where you're actually building this and giving the client permission to come in and take a look at it as it was being built?

G.M. O'Connell: The development tools that we've used in this way, and the time that it takes to do it, were much longer on the initial launch than they are now. There are so many better tools that are available. We didn't know what the heck we were doing when we first did this, nobody did. Nobody really knew what we were doing.

So originally it took about two and a half months to get the site live, and I think these days it can be done in less time. But it's not so much building the site, it's building the infrastructure for how you're going to respond to consumers, how you're going to allow them to participate and how you're going to build that over time. So the actual production model isn't that important for us, it's the thought that goes in front of that before you actually produce, and [that] takes a considerable amount of time. You've got to get a lot of people on the brand side and on the agency side involved and go through a lot of different iterations, and actually do testing of consumers beforehand. That takes the time.

In terms of staging servers, we didn't when we launched this thing. We do with other clients right now, so it really depends. If the question is if that's a good way to go, I would respond that is a good way to go.

W: My question is, "Has anybody done any research on how [Zima's] sales has increased since a site has been put up?"

G.M. O'Connell: Yes. The way we measure it is on a person-by-person level. The actual sales of Zima have not increased in 1995 because there's a huge initial spike of trial, and with any new product introduction you get a surge on trial and then the key is conversion. So if you look at, as the gentleman asked earlier, how you track that, specifically to the Web site, that is difficult. You can tie it back to some specific individuals, given promotions, but over time it's a little bit more difficult.

W: I was wondering, you said there was about five hours worth of information in that site, and I'm wondering, in your opinion, how much of this comes under specific product focus and how much is more off-shoot information and fun.

G.M. O'Connell: It depends. If you count the links, if you count where you can actually go with the links, then the model collapses, but I would say that 65% or 70% is product-focused.

W: How would you define a relationship where your Internet zoned two people now. If you're a publisher, define the relationship between publisher and other publishers on the Web: whether those publishers are other advertisers or publishers or other media-type vehicles who have now entered into Internet publishing.

G.M. O'Connell: What our relationships are? They're not with other advertisers, per se. I think there are two models that you see in the way "published" content is developed. One is derivative from existing publishing brands whether that [inaudible] or whether that is Pathfinder with Time, Inc. I think that's very dangerous. The tendency there is not to eat your young. You try to leverage off your existing brands and not kill your existing product, and that's very dangerous. Anybody who has developed a Web-centric product that does not have a parent to answer is basically, in my mind, trying to kill off... You're all competing for rep time or information-seeking time and your motto should be, "I want to slay the dragon." We don't care

who wins out, generally, and we work with bulk. We don't generally work right now with Zima, and I think that's unique because it is an alcohol-based product that a lot of other advertisers don't want to work with.

M: It seems as though you've managed to work a lot of branding into your site, all the way from a video game to the icons. Have you received any negative reactions from the Net community to all this branding, and where do you draw the line between branding your site and what the Net will accept?

G.M. O'Connell: I think there's a certain expectation that if you come to Zima.com you're going to get... and I don't mean that facetiously at all, I think that's one of the reasons you come to it. In that regard I think you get what you expect you might get. What we want to do is just to provide a great place for [people to] come and a context for them to communicate with each other around the brand. If we can achieve that, we've basically done our mission and we want to do it in a way that you can't do in print, that you can't do in TV, that you can't do using other platforms.

I think the ultimate compliment gets back to what I said before about the bar and restaurant guide: that's an information product that happens to be brought to you by Zima but you're going to go there simply because it's the best one that's out on the Net right now. Or you might play Caption Contest because it's a lot of fun, [even though] it happens to be based around the Zima product. It's a fun way to use the Net in a way that's really never been used before.

M: In the context of your comment about MIS people wanting to be creative directors, I'm interested in your thoughts about the role of the Zima Web Master.

G.M. O'Connell: What is the role and responsibility of the person who is maintaining the site, per se? [As for] the people who drive the content in the site, there's a creative director, there's an art director, there's a copywriter, and there's, essentially, a programmer. That programmer is probably one of the most creative people that we have, and we talk about MIS directors becoming creative directors. It's only dangerous if they're the ones doing the aesthetics, in my opinion. When they can work with the copywriter, I think the real creative genius, in our shop anyway, comes out. Copywriters working with programmers. How the hell can we use this thing that didn't really exist that much three years ago in a way that's never really been done before, and you've got to think about what's possible, what you can imagine, and then what's possible. And so it really requires a very creative pro... if you want to call it an MIS guy [inaudible] programmer, do that.

The Web Master is really responsive. It's an operation position within the context of what we do. It is not the most glamorous position. This varies around a whole bunch of different companies, but for us it is extremely important when it's your job to make sure that the site works. That's really what the Web Master's job is, that things are done the way they should be done.

M: You commented earlier on [the fact] that it took quite a bit of time early on because there was a lack of tools. Could you comment on what tools [you] use today, the type of tools that have helped you to increase productivity?

G.M. O'Connell: I'm probably the last person who could make a good comment on that in our shop. I'm not really involved in that. I'd be happy afterwards to tell you, to give you the name of

the person at Modem who is basically in charge of that. It's not only a question of tools, it's a question of becoming comfortable with designing for the medium, too. It's a little of both. But you see your productivity go up over time, as with anything else.

W: I have a question about the Caption Contest. Did your client put any restrictions on you as far as any controls to prevent any kind of poor taste or profanity, or is it just a free-for-all? And how are people behaving?

G.M. O'Connell: I won't say it is not censored. Everything that does go through gets seen by the brand. There are things you can get that you might not expect a brand to put out there, but we're not going to put anything out that would denigrate the brand in a big, big way. So it is censored, if you want to call it that. It's modified.

M: [inaudible] came to you with a new product and said, "OK, the target is women thirty-five plus," how would you respond?

G.M. O'Connell: I would want to know what they're trying to... you know... are we going to launch this product and can you help us. [inaudible interruption]. I would say right now probably it is not [inaudible], no.

M: You had mentioned that people go [to the restaurant guide] specifically for restaurant information. Do you use a spider to find new restaurant guide sites, or do you have someone on staff who surfs to find those?

G.M. O'Connell: I'm not sure exactly [what are] the tools that we use to do that. In fact, getting back to the gentleman who asked about the Web Master question, that is actually one of the things that the Web Master is in charge of, checking out new links, and that's one of the tools that we use. We're working on tools that do that and also on tools that really track where the competition's links are and everything else. There are so many tools that you can use to acquire information right now that are very, very powerful and a lot of the companies that are developing those right now are out on the floor.

M: The Internet [inaudible] itself really well for specific target marketing. Your product and the demographics that were existing on users matched very well. As the demographics broaden considerably, and you're dealing with services that have very broad appeal, talk briefly about some of the challenges in trying to be engaging in a more general sense without doing things that turn off other parts of your demographic's target audience.

G.M. O'Connell: I think, the big problem... nobody would say, "OK, who watches TV?" It's who watches what program. Who reads what magazines? As the market broadens, different demographics, targets, are going to go to different places. I think ultimately where this goes, and we talked about advertiser push and user pull, [is that] advertiser push is going to matter much, much more next year and even more in the following year.

When we're able to get our messages and involvement tools in front of the right people, regardless of where they are... The key is finding the right people and the right context and then matching those things, so you've got smart, addressable advertising. That really is what the Net is going to give birth to. Right now, because the Net isn't that intelligent, we can't really do that. But, ultimately, publishers are going to get extremely wealthy, more so than they are today, because media will become worth twice as much if you follow [inaudible] what John

Wannamaker said years and years ago, which is, "I know I waste half my advertising dollars, the problem is I don't know which half." Well, you're going to know, you're going to know which half you're wasting.

Basically you'll be in a position to find that out, and if you can make your buys twice as effective because you're buying people not property, essentially, media becomes worth twice as much.

M: The line of distribution: How did the distribution channels, that is the beer distributors, retailers, [inaudible] get behind that? Did they feel that that was worth dollars, being channeled into this new area, and if you have [inaudible] any point-of-purchase that you did that might have tied directly into Internet devotees that were able to pick up tearsheets or anything of that nature.

G.M. O'Connell: Yes, there are three things. First of all, it went over really, really big with distributors. Every year in [inaudible] there's a distributors' conference and I was amazed [that] you don't run into a distributor who is generally wearing a three-piece suit. I couldn't believe how connected a lot of them already were. I was amazed, and they were all over what we were doing, even more so than a lot of the senior management was at Coors, quite frankly. So, it was a huge hit with them—very, very surprising to me. I couldn't believe it.

There were three programs that we ran that got out onto the floor. One was an impact with AOL that was very successful. A buddy of mine [who] worked at AOL says that we're putting all the disk manufacturers out of business because they'll send you one every second day. We actually put some [out], and tested a program with the brand together...and it did not work very well. There are two keys to that, one is get the product out onto the floor and hope that it'll pull through. But just getting the product out on the floor—the shelf-space game—is a key thing.

The first time we went out, on the back of the Zima label, we printed the e-mail address, and there's some amount of spin on that. Then, ongoing, it's just on the label. But we didn't really promote that in a big way. The AOL promotion was the biggest one.

W: You commented that every targeted message is measurable for full budgetary accountability, could you elaborate on that?

G.M. O'Connell: I knew I shouldn't have put that one in there. Gosh, where should I start? It's both banners and we have a model, the [inaudible] point that refers to... We have a model called IRIS that stands for Internet Reach and Involvement Scale, and I don't want to get into its mathematics. But this is how we actually evaluate media buys on the Internet. It's based on a model that is print, and it comes out of the print world. It's a hybrid between a print-model evaluation, and a database marketing evaluation. So we're able to basically track on a per communications basis, per targeted message basis, what that really costs us.

M: Carrying on from that, is there a mix here, or would you at some point suggest that the media spin be completely on the Internet?

G.M. O'Connell: For the brand?

M: Yes. I mean, if you're getting more efficiencies, is there still a need for conventional media, or does it disappear at some point?

G.M. O'Connell: Well, we spend maybe 5% of the brand's budget, which is still a huge amount, on interactive. That's a rough guess, we're not even sure what it's going to be in 1996 at this point. So I would not suggest that it all goes into interactive. I think that you also have to remember, as I said before, a lot of what we did a year ago was a leap of faith.

On the part of the brand, we knew it, and if you're a marketer, you've got to reconcile two things: the inevitability that digital communications is going to happen and you've got to be there in some way, shape or form with the uncertainty of when that's really going to rock your world, when it's really going to matter to you in a big, big way. And it's that reconciliation that's key, and it's a timing issue. I think in that economist's article I mentioned earlier, they've got an interesting point, that is: this form of digital communication evolves out [of] and incorporates other media platforms like the telephone, like TV, that makes it much easier to control, but has addressability and functionality to it. So marketers very well might start spending money on digital communication that they don't even realize has been transferred into this middle arena. Video is still video, you know, a computer screen is still a computer screen, or a computer screen is a screen, a television screen is a screen, and getting people to relate to what happens to be on that screen is the job of advertisers, whether you're doing digital communications or one-way broadcast communications.

Andrew Jaffe: Let's take a few more questions.

M: Just one real quick one. You're hosting outside. Any plans to bring that inside, any reason to?

G.M. O'Connell: No. No, we do not want to be in the hosting business. AT&T is going into the hosting business, if they can plug a client.

M: I guess that you had some good and bad results from specific areas you've placed banners [in]. Can you be a little more specific on what worked well and what worked poorly in terms of wear, and how you might have changed your focus to make it more efficient?

G.M. O'Connell: I can't really get into specifics. I don't really want to talk about specifically what worked and what didn't. I think what would be interesting, what I would say is the most interesting case and is responsible for building the model for this whole banner, was when *Hot Wired* launched. Is anybody here that was involved in *Hot Wired* by any chance? Anybody advertise with *Hot Wired*?

You have investment with *Hot Wired*, right? [inaudible participant's response] It was [the] damndest thing. About a year ago it was the hottest media property I've ever seen in my life. It was completely over-subscribed. We had to fight to get two of our clients in there. We paid through the nose for it, we paid big. To get back to the question that was asked over there, from sort of a cost-per-interaction basis, it was too big, it was too much. I wouldn't pay that kind of money now, but at the time it made perfect sense, because if you were a brand that was on the emerge, and you weren't on *Hot Wired*, you were not where you needed to be. It was an ego buy, but it set the stage, because after that, [there were] no negotiations, they didn't have to negotiate. Ten or twelve weeks, thirty thousand bucks.

You know, that's it, you want in, maybe we find some space. And they sold it very well, and it was over-subscribed. As soon as that happened, our phone rang off the hook, and everybody [said], "Hey, we've got a property, ten weeks, thirty thousand dollars." It didn't matter what kind of traffic it had, that was sort of the standard that was set. I would say that through the next six months after that launch, we were trying to bring people back to the fact that a *Hot Wired* model was not the model, and it had to work a different way. But everybody

expected to get thirty thousand bucks for ten weeks. No matter what the traffic, you know, it didn't matter. That was almost the standard at that time.

People weren't really concerned about whether it was delivering anything, they were going after the ten weeks for that amount of money.

Andrew Jaffe: OK, last question here.

M: You were saying that with Zima 2.0, you're going to build to Netscape 2.0 standards, and I'm wondering how you do it in designing a Web site and all that. Do you take into account all the multiple browsers out there?

G.M. O'Connell: That is a really, really, really good question. I think the short answer is you can't. I have this slide that I presented at Comdex and it got a lot of cheers and a lot of boos. It was a comment on what Microsoft was. It lead off with, "I'm with Microsoft, and I'm here to help," [just] like the government. And I'm afraid that Netscape might be getting into that position, where pretty soon you're going to have Jim Clark showing up and saying, "I'm with Netscape and I'm here to help."

But Netscape is the standard, and I'm not sure what that standard means, or where it's going, or what part of the communications chain you need to occupy to become the next Microsoft. I think that's very unclear. But right now, they're kind of controlling that. They're not yet making money on it, but they've got their hands in every single piece, from server through development through browsing, and a lot of different measurement places in between. We're where the users are and, by far, most of them, especially for a brand like Zima, are using Netscape.

Andrew Jaffe: Great, thank you very much. [applause] G.M. will hang on here for a minute or two if someone has any individual questions, we're going to reassemble at 1:00 PM for "Virtual Reality."

THE POTENTIAL OF VIRTUAL REALITY FOR CHANGING THE RETAIL LANDSCAPE: WILL AGENCIES OR SPECIALISTS DESIGN THE NEW FRONTIER?

MODERATOR

Andrew Jaffe

Vice President/Executive Editor, *Adweek Magazines*

SPEAKER

Rob Gemmell

Creative Director, CKS Group

Andrew Jaffe: This next presentation is to take us, really, into the future. All of this is, as the last speaker mentioned, is really so new. Somebody at the break came up to me and asked me, “Is there a media company that has specialized in digital only?” And I’m not sure I know of one. I know of ad agencies that say they only do digital. But I know of ad agencies that have interactive groups, and within that group, a media-buying unit — big agencies. But I don’t know of anybody out there as an independent who’s claiming this expertise in exclusivity, in a total focus. So it’s a reminder of how new all this is.

And yet a year from now a lot of the things we’re presenting today “oh yeah, I know about that, I know about counting people, we do that; I know hits don’t matter, we do that.” And when you design these programs, you try to think of these things. Well, where is this all taking us?

One of the tools that is going to become even more important as we get bandwidth is going to be virtual reality. I believe Metromedia has some magazines in this area. I know a lot of people in this room are familiar with it and have seen it demonstrated. But how many of us are actually designing virtual reality products for our clients? And how many of us are using virtual reality programs in our agencies to help clients see things that they need to see?

I feel that CKS Partners is one of the leaders here, and perhaps it’s because of our closeness to Apple. Most of the partners came out of the Apple culture. Apple is working very hard on *QuickTime VR*, and one of the reasons I got an idea for this was by attending the Apple’s New Media Forum in New York, where they started showing some of the advances that are going to happen in the next two years in VR.

So I turned to Mark Kvamme, and Mark couldn’t be here today, so I asked Rob Gemmell to come. Rob is, as you will soon learn, totally qualified in this area, and in fact may have a more detailed understanding of the tools and the technology than Mark did. Rob is the creative director for all of CKS. CKS is — in the San Jose office, he cautions, in case there’s anybody from the New York office — CKS is now, if you capitalize their income, a three hundred million dollar agency with 200 employees, with offices in Portland, San Francisco, Silicon Valley, the San Jose office, New York and London.

It was started in 1987; it’s now really four companies — there is CKS Partners, which does consulting and advertising; there is CKS Interactive, which I believe has a relationship with [Interpublic], and it does interface design, marketing research, works on the Internet, and does title development. In addition, there is CKS Pictures which is a production facility that CKS bought from Apple — it’s essentially Apple’s production facility; and there’s CKS Media.

CKS calls itself an integrated marketing communications firm and not an advertising agency. And I think CKS Communications is another company that really is trying to move away from the advertising agency designation. I’m not sure that this is as important as the Partners feel it is, though we could debate that at some other time.

Getting back to Rob. As creative director he's involved with advertising, branding, corporate identity, packaging, and interactive and on-line media. CKS and Rob himself were involved with some of the first experiments in virtual reality environments, working for National Semiconductors and Compton's New Media. Before that, early in the '80s, Rob was at Apple doing product development and as a creative director; and later in the '80s he had his own catalog and retail firm before the partners persuaded him to come back into CKS.

I think we're very lucky to have somebody like Rob here to tell us about this new frontier, if you will, or new platform or new technology, and the uses of it in marketing. We could have gotten somebody from Apple to talk about the tools, but I think somebody applying them is always more fun, and somebody who knows our business. So with that introduction, I'd like to introduce Rob Gemmell.

Rob Gemmell: Thank you Andrew. I apologize that Mark couldn't be here today, but hopefully from me you'll get a little more of the creative stand on how we operate. Also, I'll give you a taste of some of the realities that I and the teams encounter when we're actually trying to deliver on some of the promises we've made. I think one of the best things about being in this business is that you can dazzle people with an awful lot of slick presentations and neat tricks. But then when it comes time to deliver, sometimes you learn how well you can dance.

So what I'm going to do here is I'm actually going to switch between two computers because, as I discovered when I got here, there are some limitations even with the computer technology that's rentable here in Boston. So I'm going to be giving you a text presentation in *PowerPoint*, and then we're going to be looking at some interactive presentations that are in *Macromedia Director*; and then we'll be looking at some *QuickTime VR* samples, too.

Thank you, Andrew, for that nice presentation.

Today what I really want to cover with all of you is some background — how I ended up here. Andrew covered an awful lot of it, but one thing that I hadn't mentioned to him was that I started as an artist. I studied painting, sculpture, that type of thing. Ultimately I started developing what I called non-functional furniture, which ultimately led me into the architecture program at the university I was going to.

About a year after that I was hired by George Lucas to work at his fledgling Industrial Light and Magic facility north of San Francisco, where I learned one of the most important lessons that I continue to remember today, and remind our clients of from time to time — and that is that the world's best special effects, gimmicks, gadgets, and tricks don't mean anything if people aren't interested in the story that you're trying to tell. And that was something that George firmly believed in, and he attributed that to his success. The special effects in his movies were largely in the background of the human drama that was unfolding. So I've employed that and many other lessons learned on the journey and what we're doing today at CKS.

We have what we call an integrated marketing perspective, which means that when our clients come to us and they say they want an ad, they don't always get an ad from us. Conversely, if they're looking for a packaging program we don't always recommend that either. So it works both ways. But we've grown an awful lot in the last few years, very rapidly, and we've gotten an awful lot of notoriety for some of the business practices we have — not that they're unethical — just that we're very creative.

But I would say that our growth has been based on our ability to respond to what our clients have been asking for. Sometimes we haven't responded with specifically what they've been asking for, but we've responded with something we felt would deliver what they were looking for. And along the way, we've done everything we can to exploit the technology that's available to us and that we've been exposed to. So we're always pushing the envelope in that sense.

Lastly, of course, we're always trying to provoke people — not just with the technology — but with the creative work we're developing, as well as the medium that we select to get that message across.

One of the fundamental things we believe, and it's probably because we're in the center of a valley full of engineers who are great skeptics, is that we assume all of our clients and the audience members are from Missouri, the Show-Me state. They just aren't going to buy something unless they've seen it demonstrated in as realistic fashion as possible. This has led us to the development of what I call "PSDPS." PSDPS is my acronym for "powerful simulations demonstrate, persuade, and solve," products, services, concepts, ideas, whatever it might be. So that's a very important component of how we operate.

And then lastly, something else we've learned is that if the movie is good people will wait in line. But as we've discovered, as we've sat waiting and waiting and waiting for something interesting to download, whatever we're downloading had better be very good or we're not going to be back. And in spite of the leverage that Woody Allen has gotten out of interviewing people in theater lines at his movies, our customers and our clients don't have the patience that he might have had.

What I'd like to do now is actually go through just a quick peek at how we ended up where we are.

The first things I'm going to show you are in fact 2-D simulations, but I'm going to show a few of them to you because they might inspire some of the things you're doing. They also might show you some ideas that can be leveraged in the Internet environment. So if my helper here will switch me to button two, I'll go into a couple case studies.

The first one here was United Airlines. A couple years ago we redeveloped and redesigned their identity program. I'm not going to go through that whole thing, but I want to show you the — I'm going to show you a quick peek at a program we developed in-house. I'm going to skip ahead here real quick.

One of the things that we learned how to do very quickly in the Macintosh was to simulate presentations. These two images right here are simulations of what the new plane would have looked like with the colors that we were recommending. It was effective enough that it got Steven Walsh, who is about 6'5", to stand up straight out of his chair during the presentation and accuse one of his VPs of authorizing budget to repaint one of their planes. So that was a little intimidating.

Another thing we did in the process was we simulated — and this is kind of as a freebie, which we later regretted — we simulated how this identity program might be extended throughout some of their terminal designs. (And that was a real plane, by the way.) And the simulation that we presented was of the San Francisco Airport terminal. Now, we did this photographically and presented it to them, and we didn't charge anything for it. We kind of tossed it in there as a freebie. But they liked it so much that they went ahead and hired an interior design firm to execute this nationally. And it was only after the presentation that we had learned that the last time they had gone through this drill they had spent several hundred thousand dollars in the creative development, another sixty thousand for the building and construction of the mock-up and so on — and we gave it away. Anyway, that's one of the drawbacks.

Another case study that I wanted to show you for a much smaller company, one of our Silicon Valley start-ups named Co-Active. They wanted to get into the networking business, but to keep it very friendly. One of the things they were very concerned about was the use of their packaging and how it would perform in a retail environment. So we simulated how different packages would look in their portfolio — I'm sorry, on the shelf — as well as simulated how it would look in the retail environment. This is a pure simulation here, which we were able to

execute a lot faster than building the mock-ups and going through different iterations. So here's a simulation of how it looked in a retail environment. Now, we crowded around all of their competitive products at that time, so you can see the amount of consumer punch and impact that this packaging had versus what the competition was doing.

And then just one more sample, for Norwegian Cruise Lines. They were exploring the notion of developing a new identity, and it helped them update their image. We worked a little bit with [inaudible] on this, in developing an identity that would also work effectively on broadcast and other mediums. These are samples of their old materials, and some materials that they produce onboard ships.

But I think one of the most interesting things we were able to do here was take images that we had fabricated as virtual blanks, and then paste onto them electronically how they might appear as executed. So that's what we're looking at right here. This is an image taken from an ad and pasted onto a luggage tag, a simulation of the identity pasted at the bottom of a swimming pool, on a beach towel.

[Here's] another version, the application on dinnerware plates, and other variations, as well as toiletries and other bathroom accessories.

So that's where we had been operating, in a purely two-dimensional world. But we had done another thing, too. Some of our clients were working on products which were basically high-tech, and they didn't have the functional versions of the products to demonstrate, whether it was to potential customers, to investors or alliance partners. One of these was Nextell Communications. Nextell had raised an awful lot of money on the market, and they were looking for other people to invest. We helped them put together a presentation which they presented to MCI and to Wall Street that allowed them to raise over a billion dollars in capital.

I'm going to give you a quick peek at this. This was the opening intro for this presentation that was given. I'm going to jump ahead here a little bit if I can. This version was also developed to be used in trade show and kiosk environments, so we've got some questions where we were able to gather some data on the viewers. I'm just going to click these real quick so I can move ahead.

And then we got into a mode where there was a menu, and you could learn an awful lot about the services and capabilities of it. But what was most compelling was the demonstration of how the product worked. Here we go through a quick demonstration, and we walk people through the various steps in operating one of these phones. It demonstrates the text and voice communications capabilities. So I'll click on this key here. This is important because I'll show you something later on where we've integrated some of these lessons with *QuickTime VR*.

And then we scroll ahead here until we get the pizza to go. Then we go through the process of ordering a pizza. Now, it was about a year after this presentation was completed before they had a functional phone, so this presentation got an awful lot of use during that year. At the time, they didn't have a Web site — it would have been handy to have put this up on the Web site.

So that's an indication of some of our thinking and how we address some of the problems that our clients have presented us with. And I just went through a few case studies there, which you saw.

One of the things we discovered, as you've discovered in [inaudible] launderings, is that there are a lot of lessons that we need to keep learning — and it's not that we're slow learners, it's just that the technology and its capabilities keep evolving, and every time it evolves, you get an upgrade in hardware or software, you need to learn the new rules. I think it's going to be an awful long time before we have hardware and software parity. One always seems to be ahead of the other — it's something we have to wrestle with on a daily basis, and one never seems to be fast enough for the other, which has led us to really and truly enjoy the joys of acceleration.

We're always investing an awful lot of money in chips, cards, and anything else that will help us accelerate what we're doing. But as we all know, acceleration is fleeting and it's not long before we're dissatisfied again.

One of the other things that we wrestle with continually is the multi-meg versus multi-gig issue on storage and RAM. There never seems to be enough space. We're looking forward to a multi-gig, as soon as prices drop to the level where everybody in our studio can be employing multi-gig drives to store images. It's been one of the most limiting factors; in fact, the computer that we have today that we're presenting on only had a 500 megabyte drive, and so I'm splitting this presentation between several drives.

And then, of course, for virtual reality and environmental simulation, the issue is rendering. Rendering is incredibly slow. This one program we used recently, when we set up a virtual environment, we set up to render, and the dialogue box came back with the ominous message in estimating the rendering time: about two months.

The next issue, of course, is that as the capabilities have increased and become more complex, the old adage that rocket science is not required has unfortunately changed. We've got some pretty bright people around who still get stumped on a regular basis. And ultimately, of course, this begs the question which was part of the title of this talk: agencies or specialty firms? Well, I'll get to that a little later.

And then lastly, having to do with reality — everybody has seen *Jurassic Park* and this holiday season, I imagine, almost all of you will see [inaudible] and the new movie, *Toy Story*, which has incredible rendering and virtual environments in it. Unfortunately, the machines that do movies and that the special effects were created on are incredibly expensive and not generally economic enough to use for an awful lot of our clients' needs. So we're always wrestling with the difference between what they want, what they've seen, and what's deliverable within their budget or the time frame that they've allowed for a given project.

Virtual worlds await, but many are here right now. We were developing these simulations which I showed you: United Airlines, Norwegian Cruise Lines, that type of thing. But we were looking for other ways of presenting what we could do, particularly when it came to packaging and merchandising programs. We really wanted to simulate the retail environment. But we really hadn't found an inexpensive and easily executable method until we saw the program *Myst*. How many people in here have seen *Myst*? *Myst* was the first example that we saw where a fairly inexpensive software program was used to create a really interesting virtual environment.

We took the lessons from that and did some experiments, and we concluded that we could do this in a fairly economic fashion for some of our clients. But it wouldn't be cheap at the same time, so I spent another six to nine months trying to convince clients to sponsor an experiment to see if we could help them.

Finally one emerged — National Semiconductor. National Semiconductor is not known to probably at least a few of you, maybe a lot of you, because they mostly make chips and that type of thing. But they decided they wanted to get into the consumer marketing end of their business and sell networking cards. But they didn't know anything about that business, so they came to us to poke around for ideas, and to create what in essence was a virtual campaign, and show how it might be executed so that they could finally make their decision — whether they wanted to pursue this path or not. So we took *Stratavision*, which was the program used to execute *Myst*, and developed a virtual environment. And I'm going to give you a sneak peek at this. We haven't shown this to many other people because this is just the first test. Unfortunately, the funding was ultimately cut as they discovered that the retail channel was already loaded.

But I'm going to show you our first pass at trying to demonstrate to them how this virtual store would work. The first image you'll see was one that was rendered using a [inaudible] method, so that we have very accurate reflection shadows, that type of thing. Now again, this is the first test, and I'm showing this in 8-bit mode, so you're seeing an awful lot of irregularities in the color. And then we set this up so that as you navigate into the store, you move almost like you would in *Myst*, in steps. But somebody could decide that they wanted to go down any of these different aisles, or they could view packages that were displayed here on end caps. Then this aisle here — we've got an awful lot of networking products. So we simply move forward as if you were shopping in the retail environment.

And then you could take a look to the left, as if one of the packages had grabbed your attention. And as you might have experienced when something has grabbed your attention, whether you're shopping for *Cheerios* or a software product, you usually scan the aisle first and then you approach — you want a closer look, so you zoom in a little closer. And then usually the last thing you do before you purchase the product, if it's one you haven't bought before and you're not really familiar with, is you want to take it off the shelf and examine it in greater detail. Now in this test — we didn't have the full execution here — but this is sort of a demonstration of how it was going to operate in the fully rendered version. Now you can see part of one of the side panels here: as you click on the side panels, the package rotates so that you can actually zero in and read the specs and information about the package and the product itself.

So this is our first experiment with a real virtual reality environment without using any of those programs. One thing I wanted to mention to you was that one of our programmers actually set this up in such a way that every single package you saw in the store could be selected and lifted off the shelf. So this became a rather large file, to say the least. But we did take it on the road with us to do some focus group testing, and we did some traditional focus group testing with packaging. And then we went to this presentation, and it was amazing to see people's eyes light up when they were able to put themselves into shopper mode and actually navigate through the store themselves. That was our first experiment.

I don't know how you felt about what you saw, but we were, quite frankly, a little disappointed that we weren't able to get a higher level of reality. And reality is the name of the game when you're trying to do this type of thing. So we went looking for another client to sponsor the next rev. It took us a while, but eventually we found one; and the client was Compton's New Media. Now, Compton's competes against Microsoft, and they had been getting their butts kicked by Microsoft — of course, almost everybody does — and they had gone through a management change. They had a new management team who wanted to come in and basically demonstrate that they could provide a lot better competitive challenge than they had in the past.

So they wanted to put together what they called a "virtual merchandising" campaign to show customers that they had the juice to basically re-introduce a product line and merchandise it appropriately. So we did some more testing.

And I'm going to do two things here: I'm going to show you some of the testing, and then I'm going to explain to you what we learned in the testing; and then show you how we finally solved the problem.

We tried to do another virtual tour and this time, rather than using the program that we had done before and creating a *Director* show, we wanted to use an upgraded version of a three-dimensional modeling program and do a fly-through of the environment.

The first experiment we performed was just to do the fly-through of the modeled environment, which was rendered in a very primitive fashion, before we actually placed the imagery in there, the graphic images. So the image is very small here so that we can get some

speed. But we're actually flying through the environment and going down a retail shelf, we're encountering some of the point-of-purchase display, samples and that type of thing; and then we're ending up in the cash register area. Now this is to be an opening loop that would do a quick pass of all the different merchandising materials that were going to support the new product line.

So that worked okay, but when it came time to actually apply the real graphics it took 38 hours for each frame to render. So we quickly decided that wasn't going to work, that the software wasn't quite there yet. And we went with another course which I'll show you now.

The testing paid off in that we didn't invest an awful lot of time, but we did find out that we had to come up with another solution. The other solution, again, employed some Macromedia *Director*, but we were able to present the environment that people would encounter in a much more realistic fashion and render it using [inaudible] images so that we have actual reflections, cast shadows, that type of thing.

Then we put this together in an opening loop which would go through the different scenes that somebody would encounter. So you can see some of the countertop display, self-shipper, point-of-purchase display and other materials. Here's an end cap, end poster, and then I think we've got a view of the front of the store, too. Here we go. We've got some hanging posters and danglers.

Now, this is an opening loop that was used for this demonstration, and it did prove to be very effective in convincing the retailers that Compton's was, indeed, committed to supporting their needs.

So we are still learning and experimenting at this stage with this process. We were still looking at lots of different software programs that we could run on a Macintosh platform, and therefore be inexpensive to use. But we hadn't found what we considered to be a long-term solution until Apple invited us over to give us a sneak peek at a beta version of what they were calling *QuickTime VR*. And the first versions we saw were very buggy, but we could see that the software program had an awful lot of potential. At the time they dubbed the *QuickTime VR* as "a spatial interactive environment for developing and viewing panoramic or object movies."

"Panoramic," as you probably know, is moving around in a 360 degree fashion, and being able to view an environment or room, that type of thing. "Object" is where the focus of attention remains static, and you move around the object. These environments were created by electronically stitching photos together. In a panorama, they would be basically done in a 360 degree circle that would place you, the viewer, in the center. In an object-oriented mode, of course, you would create this sphere of images 360 degrees around an object, around which you navigate.

But then they also introduced animation, which could be paced to [inaudible] employed, as well as what they were calling "hot spots," which would allow you, when you clicked on an object or a certain area, to launch still images, *QuickTime* movies, audio tracks, text, or other things that you wanted to launch when you clicked on that object.

I've got up here, for those of you taking notes, Apple's Internet address so that you can call and get more information. As a matter of fact, if you do contact them, they will send to you a CD-ROM disk that has all the software demonstrations that they've produced, as well as a copy of this white paper that you can print out that explains in greater detail how the software operates. At the end, I've got another slide that goes through that again if you don't have time to copy it down now.

So we were doing some experimenting with this and we thought this was pretty interesting, and we decided to do an experiment. But before I show you our experiment, let me give you a sample of how this software operates.

This first view that I'm going to show you is the Salk Institute in La Jolla, California. They placed the camera on a tripod, and basically did a panoramic view of this space. Now the way it operates is, you take this cursor, you hold it down, and then you can rotate in the space: you can pan up, you can move down within the image area, move around in the space, and if you want to you can actually zoom in or zoom out in this environment.

But this program is not limited to just pasting together photographs of environments or images — you can also create imaginary environments and do the same thing.

So this is a virtual environment. This place that you're going to look at right now doesn't exist anywhere in the universe; but we've created this environment where it certainly looks very real. You're able to navigate around in here and pan around 360 degrees, up and down; and we've got an awful lot of reality, even operating here in 8-bit mode. We can still see that in a high resolution mode, it would be very convincingly real.

And then lastly I'll give you a demonstration of how the object-oriented operates. Now this is a normal credit card, this is actually one of our guy's credit cards, and if you look closely you could actually copy down his number if you want to. So I thought that was awfully brave of him. This is a Citibank card here, and on the back, you've got his real signature, his account number — so I won't dwell too long on there in the static mode. Anyway, so you can rotate this around in any direction you want. Now it operates a lot faster, and it requires a lot less storage space if you do it against the black background, but we found some tricks that allow you to do it against the rendered background, too.

So as we were exploring this, we were asked to put together a presentation for Time-Warner Interactive, who wanted to [inaudible] for the largest-selling coin-op game they'd ever produced into the home. As a matter of fact, they wanted it over to eleven different platforms, to introduce them simultaneously; this was the first time this had been done. Not even Nintendo had done this. But they were up against Nintendo, Sega, and people with bigger budgets than they had; in fact, I believe Nintendo spent about forty million dollars on their campaign to introduce *Donkey Kong*. So Time-Warner, with a few million dollars, was trying to make it look like it was in the ten to twenty million dollar range.

So we worked with them to put together a virtual launch that would convince resellers to place a lot of advance orders, and basically lock them in. But we also wanted them to buy into the vision of Time Warner and the character of the product. So we did the whole thing in character. So, as they've described it, what they wanted to do was butt-slam the retailers into buying their product and making advance commitments during the spring quarter for the following holiday season. This was March when we were contacted, so we had to put this thing together very quickly. We didn't have much time, but we did find an opportunity here for our first use of *QuickTime VR*.

So hang on here, I need to close a couple things down before I launch this.

The product was called *Primal Rage*. For those of you who keep seeing *Doom* and some of the other "kill 'em" programs, it's very similar to that, but it doesn't use humans — it uses animals and monsters, that type of thing. But it's still a very violent game, and it's very popular primarily with adolescents — but I should say adolescents of all ages. So during the development we had to install, of course, one of these coin-op games in our cafeteria, which was used almost around the clock.

Now we put together this presentation that they could take out on the road and use at conferences in presentation suites to demonstrate what this could do and also to convince people, potential buyers, that Time Warner was fully committed to supporting it. Part of this required some level of customization, so we built in here a routine that would allow you to go through the list and select whomever you wanted to present this to, and paste their logo in

here. In this case, I'm selecting Sears. So you see the Sears logo appear there; just a nice personal touch.

And then as you go into it you've got this nice, pleasant background music that lulls you into the presentation. And the presenter can extemporaneously talk about whatever they want to until they feel that they've got their audience properly prepared for something a little different. And then when they clicked, they hear some jungle sounds, a roar, and then we enter the program in character.

Now because this is going to be introduced on eleven platforms simultaneously, it gave people a sneak peek at the different platforms and how the game looked on those various platforms.

Then we went through a lot of routines where we presented simulations of print advertising. Then we actually produced their broadcast spots. I'm not going to show all that to you today, but we did create some packaging, that type of thing, and I do want to show you that.

Now one of the fun things we did was we created this interface with sound effects. If they were in a playful mood, they could actually perform a drum solo here for their audience.

So let's take a look here at some of the consumer support material that we produce. We were in character the whole time through this presentation.

And then we gave people a demonstration of the different media which is supporting the introduction of the program. So this is just a quick rendition of a typical retail environment. The one thing that worked very well with the retailers and the resellers was the integration of *QuickTime VR* to show them the packaging all the way around and allow them to zoom in and look at the actual copy and some of the illustrations in greater detail. So these are the first views here, and I think this was, with one exception, the first commercial use of *QuickTime VR*.

So that worked very effectively. Within a few weeks, Time Warner was able to exceed their sales goals and commitment goals with that roll-out campaign.

At the time, Apple was having a tough time demonstrating and convincing people of all the different qualities that *QuickTime VR* had within it. So they put together a project to demonstrate this and serve as a case study. This project is actually laid out in this White Paper that you can get. And they produced a video that demonstrated how they actually executed the photography. I've got a version of this the I can show you at the end, but I have to reformat the monitor to do that.

I'll show you another simulation that is very similar to this that we did. But what they did was integrate *QuickTime* videos with the *QuickTime* virtual reality, and they created a walking tour of the Apple Company's store, selling computers and apparel, that type of thing, all supporting the Apple brand. But they demonstrated here very convincingly your ability to browse, compare, shop, get detailed information on products as well as specifications. And if you wanted to you could potentially order them, although they didn't set it up that way.

But what was interesting about this was that they were able to execute it for something considerably less than the huge budgets that were required for some of the other solutions that we had seen. In fact, they will tell you in the document that the resources required were eight weeks to execute this, nine people were involved in the team, and they spent \$31,000. You can see what I've got up there in parentheses though — they weren't looking to make any profit on this.

So we took a look at what they had done and felt that we could do something similar, but we knew that we just had to basically do it ourselves. We weren't going to find somebody to sponsor this effort. So we actually did our own version, which I'm going to give you a tour of right now. And what we wanted to show people was the environment that our interactive folks operated within, as well as give them a notion of what *QuickTime VR* could do. And we wanted

to demonstrate that we understood how it operated, and we that understood enough about it to execute it in an environmental fashion.

So we created this walking tour environment down here, which is actually a map of our interactive group. They've since grown so much that they've moved into their own building across the street. But here we start with this view right here. Now each of these dots symbolizes a node, and you can navigate from one node to another. So I can stand here in this node, and rotate 360 degrees. I can look at the ceiling, I can look at the floor, I can do all of that. I can't look at my toes, because we cleverly hid the camera.

And then if we want to we can actually navigate down the hallway here, move to another node, another one; again, we can navigate and panographically view what we've got going on in this area. We can move back here. We can zoom in, and I think I've got *Mr. Potato Head* here. And we added this little interface that allows you to zoom in more easily, rather than using command keys. We can zoom out; we can actually zoom out beyond where we were viewing from and get a much greater perspective on it. We can select, with a pull-down menu, different areas we want to go to or we can simply click down here on some of the other node locations. So the map is interactive, too. So we can spin around here, look at one of the conference rooms, the magazine rack, that type of thing.

So that was a very simple quick walk-through of our facility.

[Tape change]

Rob Gemmell: So we took the lessons we learned in creating this site, this interactive tour, and we looked at what it took us to do this. And what we were able to do, what you saw there, took us two-and-a-half weeks; we had a team of six people assigned to the project, and this was their first time to execute it. It cost us about \$20,000 in time to execute it.

After this was executed we started talking to various clients who were doing an increasing amount of Web work about some potential applications where could embed, perhaps, some of these *QuickTime* VR movies. Apple, at the same time, was working on a deal with Netscape that would allow them to do the same thing. And fortunately, they've been able to work something out, so that you can, in fact, embed *QuickTime* VR movies in a Web site.

Now we had several different clients who were looking for this type of thing. We'd been doing an awful lot of work for Internet MCI. Every two weeks we put together new selection of content for their Web site to keep it updated and fresh. We were working with NBC, putting Jay Leno on-line with real audio monologue bytes, behind the scenes information, and *QuickTime* monologue movies. What we were really hoping to do, though, is do a backstage VR tour a la the Larry Sanders Show — something we knew that people would be very interested in. At the time we weren't able to execute it, but now I believe we can.

The first Web site that I'm aware of that is employing *QuickTime* VR is actually one that was sponsored by Holiday Inn for their Crown Plaza Hotel in Atlanta. And I've actually downloaded a few rooms here, where they've actually embedded *QuickTime* VR. They've got what I call a completely wired Web site, where you can do an awful lot of different interesting things to explore the hotel and learn about what their facilities can do. But they do have these *QuickTime* VR scenes and tours of their suites. I'll give you a quick view of this. If you want to take a look at one of their rooms, you can download this image. One of the great things about *QuickTime* VR is that an awful lot of the files can be fairly small in size. This one here is about 168K, so it takes just about a minute, depending on your transfer rate, to download it. And then you can navigate around the room, and get a real sense for the feel of it, the type of furnishings, space, and how you might feel venturing there.

They've also got a view in here of one of their suites, if that was just a little too claustrophobic for you. And I'll give you a sneak peek at that. After watching these, I have to admit though, I've got some ideas that I would like to suggest that they pursue further. Here you can see that they've got a TV cabinet. Wouldn't it be interesting if they developed that as a hot spot? When you clicked on that TV, you could see what movies might be available on-line, that type of thing. If you click in the kitchenette, you might find out whether they have a self-help bar there, or whether you have to show up with your own goodies, your own bottle of gin, or what have you.

So that was the first interesting application of *QuickTime VR* on the Web that we saw. We've been working with a number of other clients doing some interactive things and exploring what the capabilities are of *QuickTime VR*. One of them is GM, where we've been playing around with some ideas that they might use with their [inaudible]. This is a CD-ROM experiment; basically what we were trying to do is push the limits here. We created what you will see is what we call addressable interface, so the interface is user-definable depending on some of your preferences. The version I'm going to show you is for a person who comes from a sort of a "show-me-more-cool-stuff" attitude, but also for somebody who is more — just wants to see the specs, that frame of reference. And then we sneak in there, of course, a little entertainment.

Now to show you this, I'm going to have to shut all of this down and quit. It takes a couple of minutes for this to load. But one of the things that the team was trying to do here was not just show GM some of the different ideas that we had for how they could demonstrate the product and supply people much more entertaining information about the [inaudible], but also we have this team of people who are really trying to push the limits of the software program, and because we've got programmers on staff sometimes they go in and rewrite the code a little bit, too. And they try to amaze us. So we saw some examples of that here, which I'm really pleased that I can show you today.

One of the things they do after they execute one of these presentations, if they have time, is they go back in and try to figure out how they can re-configure it so that the load time is quicker; and in some cases we've been able to cut load times by 50%.

So here's a quick peek at the one of the interfaces that we've developed. So in this selection here, let's say we're going to look at the [inaudible]. We click on it, and this could be a touch-screen interface, or it could be mouse/cursor driven. And so a panel goes back to review a hidden button panel. And if we click on the option "Exterior" key here, we can pop a very simple *QuickTime* movie that will give us a view of the [inaudible]. Now this isn't an actual [inaudible], this is a plastic model that we assembled and then built for this demonstration. But you can see that you can rotate it and get an awful lot of detail about it. We've actually gone through some models for photographing an actual [inaudible], and I can tell you it's not a simple task — you have to build a rather expensive rig, but we do know how to do it now.

So that's a quick tour, an external tour using *QuickTime VR*, of what the [inaudible] looks like in back and all the way around. What I'd like to do actually here is — now we've got this node also where you can go in and you can take a look at the engine, and then based on your interest level you can zoom in and prompt information and get technical specs and actually call up the manual to learn how to maintain this truck, if you're somebody who is into maintenance and that's your first priority.

Or if you're much more interested in the interior, the comfort of the ride, the experience of driving and spending time in the [inaudible], you can click on the interior. And we've even provided some engine noise here to get a sense for the quietness of it. Can you hear that? Can anybody hear that audio? Can we turn up the volume a little bit? Can people hear that audio now?

Well, let me continue here while the audio is adjusted. I'll just re-launch this. Maybe we'll get some audio this time. One of the best things about *QuickTime VR* is what you can do with the audio. You can assign directional attributes to audio, so that when you're looking in one direction, for instance, you might not be able to hear anything; when you look in another direction you might be able to.

In one of the demonstrations that Apple gave us there was a scene where somebody was on a beach. They do a complete pan of the ocean and then the land; you've got palm trees, that type of thing. And then down at the end of the beach there's a little cabana; if you're standing there and you zoom in on the waves for instance, you can hear the volume of the waves increase as they come crashing in. If, on the other hand, you're more interested in what's going on in the cabana, you can zoom in on the cabana which is way down the beach and you start hearing some tin drum music from the Caribbean.

All right, we're going to improvise here — and then when you zoom in on the cabana even further, you can zoom in at somebody sitting at the bar, and you can actually eavesdrop on a conversation they're having with the person sitting next to them.

All right, I'm going to go through this again — is everybody able to hear that? Great. Now when you go into the interior, we've got what would be the sound of the engine background audio going. Is that loud enough for you? Everybody can hear that? Great. Now you can take a look here, you can zoom in, zoom out on the dashboard, the control area, that type of thing. And then if you want to, you can pan up and take a look at the overhead console, the lights, that type of thing, storage for your sunglasses. Or you can rotate and get a better view of the rest of the interior. We even simulated tinted glass in here. But as you pan to the back, and you notice that the back hatch is open — and what do you know — there's a trickling brook out the back, and you're able to hear that.

And then as we continue back around to the front, you can zoom in and see some of the leather and detailing on some of the interior panels; you can see the drink holder there. And let's say we want to learn more about the stereo system, and maybe the air conditioning system within the [inaudible]. So I'll just click on that, and this is a hot spot that we developed.

Now we've got air conditioning, we've got radio. Just for fun, let's listen to the radio. What we really want to hear, I think, is some driving music. Let's see if we can get some driving music. Tom Jones is, in my view, driving music. This is nice, but it's not quite driving music. And that certainly isn't [inaudible]. And so let's go for the tape — there we go, that's driving music. There's another great song on this tape, too. Maybe I should fast-forward to the next one. Maybe I went too far. Let's see what it sounds like in reverse. That was interesting. Now I'm kind of curious to hear what it sounds like with the air conditioning on at the same time that the radio is on. Can you hear that? The air conditioning is on? That's standard [inaudible].

So that's a quick demonstration of some of the other audio capabilities of *QuickTime VR*, too, which we've been using.

I'm going to go back and conclude the presentation and then if there's time — let me see how we're doing on time. So we've got time for questions and answers here, too.

One of the things that we learned in executing this, however, was that if you really want reality, you need to be able to download these images and project them in a high-resolution mode. All the images you were seeing today were in 56-color format, so 8-bit. Some of the executions that I demonstrated to you are spectacular in a high-res fashion. In the coming year, as Metromedia, in their partnership with Netscape and other folks, *Java 2.0*, and [inaudible] evolve and are introduced, we should have better 3-D capabilities that can take advantage of some of what's capable right now in *QuickTime VR*.

I'm going to jump ahead here to where I was. And I just wanted to do a quick review of some of the issues that we've encountered. And then here's some applications. I don't know if

any of you are working on projects right now where this has some bearing, but these are some that I just thought I'd stick in here just to provoke some thought. Actually, the first one here, Andrew told me about; I haven't seen this one demonstrated yet. But he saw a demonstration of Ticketron where they actually had a *QuickTime VR* movie of a stadium, and you were able to navigate around the stadium and select different seats and get a sense for the view of the field and those various seats. I can imagine how this would be very helpful. In fact, if Dave is here, he might want to talk to Ticketmaster about something like that.

Another idea here is an advanced tour of unfamiliar places. We saw some examples of what one hotel is doing there. Airports, museums, schools — if you have young kids like I do, who are starting a new school and are very nervous, this would be kind of a fun way to warm them up to the idea.

How about a demonstration of the unique features available from a dishwasher? And viewed from the interior?

Another idea here is an arthroscopic dental tour of your mouth, or a real heart. Or an artificial heart.

And then some others here, some that kids might enjoy: the travels of a gopher, maybe a tour of Winnie the Pooh's lair, or inside an ant colony — and that might be something good for an on-line encyclopedia.

So there are scores of other ideas. In fact, I was listening yesterday as Dave was talking about his Web streaking that he wants to be able to deliver next year, and I was imagining what level of detail and reality this could add to that.

In spite of those great opportunities there are some issues. Some of these I've talked about — memory is one. As big as the memory on our computers get, we will always be looking for more. Same with storage space. Internet download speed right now is typically one to two kilobytes per second, so some of those *QuickTime* movies you saw, like the tours of the Holiday Inn, take a little over a minute to download. A little over a minute is far too long for some people. Sometimes your patience is going to dictate that it has to be five to ten seconds. The smallest *QuickTime VR* download file that I've seen was about 25 to 35 kilobytes, So you can get them pretty small, but it was a very simple pan.

One of the things that we've learned when we were helping Apple introduce the *Newton* — which unfortunately hasn't done better, but I'm happy to say that version 2.0, which will be shipping soon, is a quantum improvement. Just for fun, we took an interactive demo of the product which we'd been using in point-of-purchase displays, and we put it on-line with CompuServe and America Online; and in spite of the fact that it took 27 minutes to download, within four weeks of us posting it and doing absolutely nothing to promote it or let people know that it was there, there were over 3,000 people who downloaded it, waited the 27 minutes, went and watched some TV, did some wash, I don't know what — but they waited for it to download and responded very favorably to the demo that was given.

So one of the things we learned was that as a rule, you want to keep these files as small as possible, but if you have something really important that you want to show and it's something people would be genuinely interested in, they're willing to wait as long as you set their expectations appropriately.

Regarding motion quality, I would characterize *QuickTime VR* right now as adolescent but spirited. In terms of resolution it's still grainy, as you saw here, but it's improving, and with every new person who decides to employ it and experiment with it Apple is further encouraged to refine it and put more resources behind improving it. So I encourage you to make use of it as you see fit.

Right now rocket scientists are required. You need to have some pretty fluent Macromedia *Director* skills. It's also helpful if you're fluent in lingo to put together some of the presentations like the ones I showed you today.

And then lastly, the issue of specialists versus agencies. In a sense, this is open-ended. For us it comes down to: are we going to be doing something frequently enough, and have enough of a revenue stream to dedicate and set aside for bringing people on full-time? I know an awful lot of agencies are outsourcing us right now, playing a wait-and-see mode. Quite frankly we've done that too from time to time; although as Mark would tell you, we're probably quicker to jump and commit ourselves to something like this than a lot of other people just because of the people we have on staff and probably the influence of where we happen to be located.

That's basically what I had to talk to you about today. I'm quite happy to see if I can get the Apple store up and going for you, too, if you'd like me to. I've got plenty of time here for questions.

Andrew Jaffe: Why don't we take some questions first, and then if people want to come up at the break, you could do a little demo. Can you bring up the lights?

Oh, by the way, I was supposed to mention there — is Don [inaudible] here? Don, there's a message for you back at registration. Is [James Herring] here? There's a message at registration, I think it's fairly important, so you might want to break off and go get it. I'm sorry I didn't get to you earlier on that.

All right, any questions? Where are we going to start?

M: Given that there's a lot more [inaudible] in the Web, rather than *QuickTime VR*, I'm surprised that you guys focused so much on *QuickTime VR* rather than *VRML* or *VRML+*, or something like that. Could you address how you're picking standards? I mean, I think you're the first person outside of Apple that I've heard call *QuickTime VR* any kind of VR standard, particularly for the Web.

Rob Gemmell: One of our concerns about *VRML* and *VRML+* is that it's basically — what our guys have learned is that there might be some compatibility problems between the two different versions, and we're trying to create solutions that will work cross-platform. *QuickTime VR* works in a Windows environment, works in Macintosh environment, works in UNIX. And so we just see the application as being broader at this time. Six months from now that might change, I don't know.

M: In the traditional advertising model, do you have the copywriter and the art director working together as a team? Does this mean that there is now a third person involved, or is it a different kind of relationship that occurs when you bring programming in?

Rob Gemmell: Actually, we have a number of different titles for people who play different roles in this. In developing the interfaces, we actually have cognitive scientists on staff. People [inaudible] are best known away from Apple, who spends an awful lot of time being very concerned with people's interpretation of environments and interfaces, that type of thing.

The other title that we have, which we didn't have in our other businesses was simply "interactive producer." This is somebody who may not be a designer, they may not be driven by the creative primarily, but they have a really good understanding of the technical limitations and also capabilities; and they have some project management capabilities, too. So producers play a key role.

And then we have people who are interactive designers, and they're people who are traditionally graphic designers, but they've become very fluent in some of the interactive programs and the medium; and they think in terms of interactivity.

And then lastly, we do, in fact, use copywriters in these projects. They put together the story lines and try to keep them compelling. One of the things that we can be guilty of, like anybody else if we're not careful, is we get sucked into the cool visuals and we haven't put enough emphasis on the story, the message, and that type of thing. So we've got copywriters who actually devote themselves entirely to interactive presentations for the sites.

W: Where does the GM piece run? Did you have to pay for the rights to the music?

Rob Gemmell: This piece is not running yet. This came out of our lab and was done two-and-a-half weeks ago. And so this is a sneak peek at something that's not quite out there yet.

W: Music?

Rob Gemmell: Music rights? Well, this is an experiment just to see how it worked, and so I'm not sure what was done there.

M: [inaudible]

Rob Gemmell: We're looking at laboratory solutions, not solutions that are out on the marketplace.

W: You mentioned that there's a couple of helps for — instead of having to rely on a black background for this, that we have the storage and the file size problem, so there's a couple of examples that might allow you to still keep the backgrounds other than black.

Rob Gemmell: That's right. In fact, as you saw in the GM demo when we were rotating the car, we did have the leather-grain texture behind it.

Andrew Jaffe: There's a question in the back, and then I have one or two.

Rob Gemmell: Did that answer your question? I'm sorry.

W: [inaudible]

Rob Gemmell: Oh, the question was: what will we do operationally to reduce file size and still keep the background?

Actually, backgrounds can be one of the biggest hogs of memory, particularly in some of these virtual environments. And so if we really want to cut it down — like we saw in the very first virtual store execution, we had no sky above the store. So that has been one of the techniques. What we try to do, basically, is keep the image area as simple and low-res as possible.

M: So you have a methodology to control production and to control production costs? In my experience, developers want to jump right in and play with something like *Director*. Do you have a methodology to control what the end-product is going to look like, and deliver on client expectations?

Rob Gemmell : You mean just telling them how many hours they have?

M: I mean, if you go back to traditional advertising again, you have [inaudible], you have [inaudible] for television, you have the story board. For interactive, you have what?

Rob Gemmell: We have a defined process that we use that is basically step-by-step. There are certainly some sections where efforts continue in parallel, but we've defined and evolved the process over the last few years that the interactive folks use.

One of the things, though, that you're probably aware of is that because this is virgin territory there's a lot you simply can't predict. And so what we've done is we've tried to set limits on what that's going to be, but we've also asked our clients to buy into that. So when we start one of these projects we usually do it multi-phase. Phase I is just figuring out what we want to do. Phase II is figuring out how much we know about what we want to do and identifying what we don't know. And then at that point, we ask a client to commit to a given budget for what we know, and then for what we don't know we simply tell them that we're going to estimate a range within which we anticipate. But we let them know that we can't guarantee that.

Andrew Jaffe: Correct me if I'm wrong, but from [inaudible] presentation at some of my other seminars, I know that CKS has developed a proprietary electronic job jacket. The job jacket shows the budget and the clock's running, and you call it up, start working in it, the clock's running — you know how much of the budget you're using. You've got three people doing an all-nighter — that's using up the budget. The point is that they also have something where this keeps their timesheets, and all they say that the client pays anyway, and if that's the way it's arranged with the client it goes into a pool that is then distributed at the end of the month, or the end of the quarter. So it's in each person's own interests to keep it under budget. And that's another way of keeping people from just now being able to let go. Because anybody who has worked with creatives in this environment knows that they just want to keep playing with the envelope. Is that generally correct?

Rob Gemmell: That's right. And as a matter of fact, our creative and other folks are encouraged to enter their time on a daily basis, so that at any point in time, an account manager or somebody else can take a look at a job jacket folder and see where the time has been spent, how much remains. We can also track what POs have been cut for outside purchases, and see where that is, too, as the project progresses. And then ultimately predict our margin on any given project.

Andrew Jaffe: I think the question raises the point: it's very hard, from the beginning of this technology, to know how much a job takes.

M: [inaudible]

Rob Gemmell: You know, it depends on how much budget the client wants to set aside for doing that. Sometimes we actually [inaudible] an illustrator, a kind of a map of how the interactive piece will operate with the different stations, and it almost looks like a decision tree. We have done more elaborate versions where we've tied the story board into that with images, so you can actually see the progression. In some instances, we've used [inaudible] to go through a quick story board, or we've used *Director* to put together one, too.

M: I'm curious in the [inaudible] piece why you decided to build a plastic model and not do it digitally. I thought that was interesting, and there must be a good reason for it.

Rob Gemmell: Well, our first estimate for building the rig that would be required to rotate the [inaudible] in space, or position it in such a way that a camera could rotate around it with zero error, was above \$20,000, just to build the rig for the photography. So for this experiment, which was just to demonstrate some of the capabilities, it was far more economical to go out and buy a plastic model. If they decide to pursue this and make a commitment, then we will get the funding to build that rig. And we're looking at ways of doing it less expensively right now.

Andrew Jaffe: Well, that was a wonderful in-depth view of something that we're just starting to become aware of, but I think it's going to play more of a role especially as bandwidth increases and you can do more things on the Internet.

You're all aware that Bill Gates has not only started to buy electronic rights to art around the world, but he has built a virtual mirror of the Seattle Museum, where he's using virtual reality to go into the museum, essentially as a teaching tool; but I guess also an entertainment tool, a social tool. Whatever he's developing there and the programs used there can be used by the rest of us commercially down the road. You might want to comment on that.

And the other question I have is that I mention in the title how this certainly threatens the retail landscape. If any of you are buying into retail real estate firms, then you've got to be asking yourself the question: how much is going to be done in terms of virtual buying, and how much is going to be done in actual strolling malls, and physical buying? Have you done any thinking on that, and do you have any opinions about that?

Rob Gemmell : As a matter of fact, we have. We've all probably looked at Home Shopping Network; some of us have probably looked at the Internet Shopping Network, which makes available over 20,000 different products. Internet Shopping Network is now owned by Home Shopping Network, and they are trying to create, in essence, an on-line mall. They are using some rather straightforward methods for putting products up on screen, which is basically downloading [inaudible] files of products.

So theirs is not virtual 3-D, but we do have another client, they're operating only in Japan right now, they're named [inaudible], and they have developed some compression solutions that allow them to distribute [inaudible] and audio files that are in the same size area where we would want them to be for virtual environments. They have already installed a chain of over 13,000 [inaudible] mini-bars throughout Japan, and you can download any video, that could be "New York, New York," and you can see Frank Sinatra singing it, or you can just look at some interesting scenery and get the text or just the audio and be singing over that. Now they've clearly solved the problem over simple ISDN lines, and so we're talking to them about how we might be able to make something here happen with them.

But if I were Shopper's, or if I were a retailer anymore, and I was thinking about opening a lot of stores, I would carefully consider where I was locating them, because an awful lot of people can do more and more of their shopping on-line. People still want to do the touchy-feely type of thing, but you know, after you've done that for a little while, you kind of get a feel for what something is; and with a program like *QuickTime VR*, if you were to look at a garment and be able to zoom in in high-res mode and actually look at the fabric, and get a sense for the weave of it, a sense for the colors, and then zoom out and see it on a model or rotate around

the model and see how it might fit them — you can be far more inclined to shop on-line and save a lot of time than to actually have to drive out and try it on.

M: I had a couple of questions. Can you comment on — you mentioned earlier about having some people in-house, and outsourcing — whether the control factors are the main elements, or whether it's the perception of the client when they come in and they ask you: well, do you do these things in-house, or do you sub-contract, and who do you deal with? That type of thing. So that you have total control of the project.

Andrew Jaffe: Can you comment on what the defining factors are?

Rob Gemmell: We use freelancers, but we use them primarily when we have a ton of stuff that needs to get done real fast, or when we're shopping to hire somebody and we want to try them out. When we find good people we want to make sure we've got them locked in, because there's a dearth of them out there. There aren't a lot of people who have studied programming and also have degrees in design or are really good copywriters, or have very good project management skills, and are fluent in some of these programs and their capabilities. So when we find one, we want them on board as quickly as possible.

Andrew Jaffe: How do you handle the issues of, if you develop these different functionalities for the Web sites that you're creating, who owns them?

Rob Gemmell: That's a very good question. In some cases we are licensing some of our solutions to our clients.

Here's my personal view: my personal view is not to be pushing the technology just for the sake of the technology, in spite of what I've just shown you. My personal view is to really promote what differentiates you from everybody else out there. If it's that you're creative, then I would emphasize the creative work that you do. If it's a specialty within a certain marketplace, whether it's retail or it's automotive or whatever, I'd play that up. But I think whether it's on-line or in other mediums, I think the name of the game is still differentiation — what makes you stand apart from your competitors.

M: How fast are you growing, and what kind of positions do you find yourself looking for now?

Rob Gemmell: We are actively looking for people who are very comfortable in both [inaudible], *Lingo*, *Macromedia Director*, and *QuickTime VR*, and those types of applications. So I invite anybody to contact me.

M: Do you find you're getting them right out of school, or do you find you're getting them from other agencies, or from somewhere else?

Rob Gemmell : A lot of the people who are working in our interactive group we are either getting from school or we are convincing them to join us after having operated as freelancers. There aren't a lot of agencies that have people that we can steal in this area, so we've been bringing people on board and then devoting an awful lot of energy to training them on what they're doing. And then teaching them marketing, too. We can't forget that this is just a medium, and the content is still very, very important.

M: As you invest in your people and their education, that certainly has a cost. Have you found that you keep those people? Do you contractually enter into an agreement with them?

Rob Gemmell: We don't have contracts with anybody, but we give them a piece of the company and they share in the profits.

Andrew Jaffe: All right. If anybody has any further questions, they could come down front. Now we're going to break for a half-hour, and we're going to try and start the next presentation fifteen minutes early at 3:15. My associate, John Lerner, has just arrived. He's in the back demonstrating Ad Week Online, which is, compared to everything else we saw, pretty pedestrian, but has a good search engine. It does its job. So take your break, and we'll see you back here at 3:15.

INTERNET PUBLISHING: ISSUES AND DIRECTIONS PUBLISHING IN THE DIGITAL AGE

MODERATOR

Jane Dysart
Partner, Dysart & Jones Associates

SPEAKER

Daniel Pelson
Vice President, New Media Productions, Icon International, Inc.

Jane Dysart: Good morning and welcome. I'm Jane Dysart and I'm going to be doing some introductions this morning in Internet Publishing. Our first speaker today is Daniel Pelson, and he's going to talk to us a little bit about publishing in the digital age. Dan is currently Vice President of Icon International, Inc. and General Manager of Icon's new media production. Icon creates, produces and distributes that key component that we heard about a little bit earlier today, content via the Internet. Dan is a founder of *Word*, a sponsor-supported publication which was recently named best non-print magazine of 1995 by *Folio Magazine*. Prior to joining Icon Dan was at Sun Microsystems where he was responsible for incorporating Sun's technologies within the media industry. So with no further ado I will introduce Dan, and please welcome him.

Daniel Pelson: Thank you. Can you all hear me? Again, I'm Dan Pelson, Vice President of a company called Icon, and also General Manager of it's new media productions group. As Jane just said, we are responsible for launching and creating content, as well as joint-venturing with other media concerns to distribute and produce their content. I'm going to try not to make this too much of an Icon pitch; hopefully it won't be an Icon pitch at all, and hopefully we'll cover more of the issues surrounding creation and distribution of content on the Internet.

Before we start, a couple definitions to give you a point of reference. Publishing, what does that mean? Well, publishing means, for the context of this presentation, media properties that are intended to generate revenue on the Internet. We are making a distinction there between something generating revenue versus a promotional site on the Net or just an open site for informational purposes otherwise.

Digital. Digital means a lot of things — CD-ROM, on-line services, the Internet set-up. For the purposes of this presentation, again, I'm just talking about the Internet and the WorldWide Web.

At the end we'll have time for questions that people want to get into, to debate CD-ROM versus the Internet or why we need AOL or all those things. I'll be happy to maybe field some of those questions with you. A lot of you are probably expecting to hear me talk about all the differences between putting out a publication on the Internet versus getting them in print or creating some kind of media property in another medium — television, radio, whatever. My message today is really going to be about the similarities between doing something within this medium versus other mediums. I think we're all caught up, for good reason, in this well-hyped medium called the Internet and the WorldWide Web. I think what we forget a lot is the basis and the foundation for creating content. Hopefully that's going to be the direction of this presentation, and we'll see where it takes us.

To begin with, I think one of the reasons for a lot of the misconception that the Internet is something that we all want to jump onto is because it's easy and really cheap. I can set up a Web site on a service for \$15 a month. It's incredibly powerful, and there's millions of people out there accessing this stuff. Well, in general those things are true.

But again, for the context of this where you're looking to create a media property that is going to support sponsors, that's going to generate subscriptions, pay-per-view or whatever it may be, something that is really consumer-driven, these factors are less significant; in other words, it's not easy, it's not that inexpensive, and although it's very powerful if you do it incorrectly it won't be powerful for you. The message here is of a very well-hyped medium with not a lot of respect for it. So we'll take it through that way, and this is going to be the basis of the presentation here — talking about the pyramid of what has to be considered when creating a presence on the site.

To quote Yogi Berra here, Yogi said, "If you don't know where you're going, you'll wind up somewhere else." I think that's very true in this medium. We work with a lot of clients out there, media concerns that are saying, "we need to be on the Net." And in some cases they have a property that they want to re-purpose for the Net. The first question we always ask is — why? And then we get a lot of blank stares.

The question is, what is the main purpose for launching a site on the Net? What are you trying to accomplish? Who is your audience? [These are] the same questions you would be asking if you were launching a magazine, the same questions you'd be asking if you were launching a television show or radio broadcast. So you really need to know where you're going before you start to consider all the components of going through creating content and distributing content on the Net.

Let's start with content. I'm going to get into all of these in more depth. When determining where you're going, research it. This is something that amazes me — the huge media companies that are launching sites on the Web that would never think about launching a print publication without data-testing it, doing focus groups, researching the audience to see what they want. They're just putting it up there, "Okay, yes, jump on, get into it." It's good for the industry but ultimately it's not great for the consumer. So the same things that you would be going through to launch any other media property you have to consider for this medium. That's one point.

The other issue with the content is that it has to be continually honed. We're going to get into content more specifically, but this is a very dynamic medium, needless to say. Again, with other properties in other mediums, in television or print — I keep saying it over and over again — those properties are continually honed as well, based on the consumer response to it. Magazines are constantly doing redesigning when they see their subscription levels drop off.

You have to be thinking in the exact same terms in this medium. Production, distribution and promotion are often, once again, sort of a belittled aspect of getting content out there. People think, "Oh, build the content, put it up on a server somewhere and everyone can get to it." That's not true. Frankly, it's plainly not true.

There are a number of issues that have to be considered with production and distribution which often become the highest cost of creating and distributing content. And of course, the promotion of it is a complex issue — and once again, we're going to get into more depth [on that].

And finally, the ability to generate revenue. You might actually need a sales force to sell those sponsorships. A lot of companies aren't thinking in those terms.

Now, content. Our producers within Icon have a saying as well; it's no "Yogi Berra-ism," but their saying as far as content is concerned is, "If it stinks, it will stink on the Web." And the point there is pretty self-evident. You have to research this stuff; it has to be good. The key to all of this, regardless of the medium, is compelling content. The philosophy of "If we build it, people will come," is a fallacy. If you build it, people may come. If it's not good, people will definitely go. So that's a process that takes a long time to figure out, how to specifically build on the Net.

Now, regardless of whether you're doing original content — and our organization has launched some original content, including *Word* — or you're building it up in an existing property, whether that existing property is a print magazine, a television show or a franchised character like Mickey Mouse that's an existing property that could potentially have a revenue generating site on the Net, regardless of where that source of content is coming [from], you have to look at the digital medium, in this case the Internet, as a unique piece. Re-purposing, repackaging also has proven not to be the most effective way to use the medium. So regardless if you're taking XYZ magazine which has 60 years of success in the print world and trying to put that on the Net or whether you're launching something completely new and original for the Net, you have to think of it as a stand-alone, separate entity.

With existing properties you do have some advantages. First, successful existing property, a print magazine for example, has already demonstrated that it attracts an audience. It has the ability to also attract sponsors you're assuming, and finally you have the ability to cross-promote from that existing property. But too often it's kind of a double-edged sword; so often existing properties and publishing companies are looking at the print medium as really the source of revenue for that property, so what is happening is they're launching Web sites that are really there just to support the print medium. If that's what you're doing, that's fine — but don't expect that to be a revenue-generating site. That's a tricky issue that a lot of publishers are having a hard time dealing with. What they're talking about, what we're talking about are franchises, media franchises that have the ability to be used in multiple mediums regardless of the medium, but they're stand-alone entities in each medium.

Word for example, right now only exists on the Net. There's no reason that we won't franchise that media property; it sounds far fetched, but there could be a *Word TV Show* one day or the *Word In Print*, or the *Word CD-ROM* or radio show. Who knows? You're seeing it happen more and more with existing mediums. Examples of that are Howard Stern, who has a very successful franchise in his talk show, and he moved to entertainment television to try to re-purpose that content, if you will, for radio. Well, there's no reason he can't, and I'm sure he will re-purpose it for the Net as well, but you have to look at it as a separate entity that will stand and survive on it's own as opposed to something that's just there to generate an audience to a radio show.

The other confusion about how to use the medium is, I think, somewhat understandable. Everyone hears the analogy of the Internet to television in the late '40s, and I think it's a pretty accurate analogy, especially when you're talking about the content. In the late '40s a lot of the television shows were based on radio broadcasts; they were literally a camera focused on the CBS Radio Orchestra for a half hour and that was the show.

Obviously that wasn't the way to use the medium, but we're seeing the same thing in this medium. We're seeing Web sites that are showing pictures of the print magazines on the Net. To me that clearly indicates that something's wrong with how they're using this medium. In fact, what I'd like to do here is actually quickly [move] over to another system

I didn't want to show this one first, but one of these things is not like the other. I'm just going to page through these here, and this is not to pick on any one in particular. Okay, quickly — there.

Now, maybe that wasn't so obvious to some of you, but to those of us who have been doing this for a while I think there's some clear differences between the four sites I just showed you. Three of them had pictures of magazines; maybe it didn't have the title of the magazine on the picture, but it was directly scanned from that magazine. [That's] not an effective way to use the medium. One of them was specifically built for the Net; I think it's clear which one that was. Now, there's an advantage in being able to build a property without an existing print

counterpart there, and we took advantage of that. Again, my point here is that existing properties have to be completely redesigned for this medium. Maybe I'm stating the obvious.

Finally, when creating content you have to educate your contributors. Again, it's amazing to me how many people have done stuff on the Net — whether it's art design or written copy — and have never been on the Net. It blows me away. Every contributor that we have to our publications, if they've never seen it, that doesn't mean that it can't be used in the medium. But we literally bring them in, sit them down and put them in front of a system and say "This is how it works." You can't expect your contributors to be able to create topnotch consumer-oriented content for this medium unless they have a really good understanding of how it works. We're talking about a non-linear environment here, we're not talking about text stories that just run down the page. They don't work. We're talking about using the medium, the multimedia aspect of it and the non-linear nature of it to make content really compelling.

All right, that's my speech about content.

Production and distribution. The point here is — and I'm not going to spend too much time on this, because you can spend a day talking about how to distribute content. The technical back-end of it is to get a Sparc Server 1000 or Sparc Server 20. Well, what's the value of having 128 megs of RAM in it versus 96 megs? T-I's or T-megabyte or whatever — I'm not going to get into that. We'll [have a] discussion at the end for questions and answers, and I'll be happy to field some of those questions if you want specifics. But the bottom line, as I said before, [is that] this is often the most expensive part of distributing content, and under the concept of distribution and production it is not given the time that it really should be given by content providers.

[I want to] talk about some basic examples here, the global nature of the Net. Everyone knows that yeah, it's people all over the world that are accessing this thing.

That means something. That means you have to have a 7 by 24 environment in a de facto way. It has to be up. [With] our publications we have backup and recovery and disaster recovery for all of them, which is very expensive. You're talking about a lot of equipment and a lot of communications gear to make this stuff work. It amazes me when we look at our log reports where people are coming in to see some of our publications. It's an incredibly powerful thing, literally coming in from [everywhere], you name the country. I don't know how they have Internet access out there, but they do. [Inaudible] Island — it amazes me that somehow they have dial-up or something. I don't know what they have, but we have a few fans up there for some of our publications.

What this basically means [is that] you have to maintain this thing all the time. It's 24 hours a day, and you see that from your log reports.

[With] multiple versions, that's a production issue. *Word*, for example, has a version that is for Netscape 1.1, and it has a version that is for non-Netscape browsers; and this is transparent to the user, but that means we're maintaining literally two versions, completely separate versions, and we have a third version that we're now in beta testing for which is a *Java* version. You can see it down in the icon boot. It's transparent to the user, but this means that we have to maintain different sets of content. A lot of it can be re-purposed, if you will, from the *Java* version to the non-*Java* version or from the Netscape version to the AOL version, but we're talking about an enormous task in maintaining the content, keeping it up to date and keeping it relevant between the versions.

Security. Transaction security — there's a lot of hype written about that, [and there's] no question it's an issue, but there are security concerns even for content like entertainment. I don't think any publishing house would let its presses be exposed to a stranger off the street walking in to see what's going on there. You have to be thinking in the same terms. No, you're not conducting transactions perhaps, but you have to be thinking in the same terms that this

has to be a 100% secure site that hackers won't have access to or curiosity seekers won't have access to.

To put a positive spin on it, it's the dynamic nature of the Net. Again, [it's a] a production issue. I'm talking not just content but the "eye candy." The stuff that allows your viewers to know what we call "eye candy," that's something that's constantly changing. Every time they look at that site something's going to change that's going to draw people back and going to make it interesting for them. Again, [that's a] a production programming issue.

New technologies. Again, [another of the] production/distribution issues. How to you stay on top of that stuff? It's very difficult. Go downstairs on the trade show floor and you're going to be amazed at some of the stuff that's coming out: real audio, *HotJava*, *Zing*, there's hundred of things. There's obviously billions being invested in new technologies to make it easier for content providers, but you have to stay on top of it and incorporate it, because they're being thrown out into the field and to the consumer so quickly that if you stay behind you're going to look like — you know, it's not like a print product. If you stay behind, it's going to be obvious. [That's the] bottom line.

And the final issue that I want to specifically address is bandwidth. This is a critical issue. A year ago people were talking about "Do we really need a T-1 or should we go into a shared server environment that has eight other Web sites on it," and "Is this going to be capable?" Now it's the question of "Do we need four, five or six T-1s or should we get right to 10 megabytes?" and "How much is a DS-3 connection," — that's equivalent to 28 T-1s — "and how much is that going to cost us?"

The reason this is becoming an issue is for two reasons, actually. Number one, there's a lot more users out there, which is slowing down response time. In the *Wall Street Journal* today, Nielsen just released its findings on its survey and they are confident that there are at least 17 million people surfing the Web — not with access to the Internet, but surfing the Web. Thirty-four million people, they believe, have access to the Internet, and this is growing very quickly.

This is the first survey that was a real survey in the sense that they weren't serving Web users, they were serving the American household and actually Canadians. So that is obviously impacting the bandwidth issue.

The other thing is now band versus broadband to the home, and this is something you have to be thinking of today. I just came back from a conference where the CEO or senior person from every major communications company — we're talking Time Warner, TCI, the RBOCs, on and on — gave a presentation to an analysts community about where they're going as far their companies are concerned, and every single one of them stressed the importance of the Internet. What they also stressed is that they're investing heavily in bringing very high bandwidth to the home. And you know, this is not that far away. A couple of these companies said that in 1996, mid-year, they're going to just start distributing thousands and thousands of the cable modems.

And they're claiming that the speeds of cable modems — does everyone know what this is, cable modem? They're claiming that the speeds of the cable modem are three megabytes per second. Let's cut that by a third; let's say it's one megabyte per second, and say it's not going to be as successful as they think it's going to be. That still is going to put tremendous, tremendous strain on the content that people are trying to get access to. You have one T-1, which is 1.54 megabytes per second, and let's [there are] just a hundred people out there with cable modems that are trying to access that information — you're going to have a problem. So the message there is to invest now in the bandwidth, because if you're taking it seriously at least you won't be so sorry when the bandwidth to the home starts getting very high-speed.

Promotion — [that's a] very complex issue. Okay, now that we've researched our content, invested in it, built the best distribution machine that we can and hired the best

production capabilities that we can, how do we let people know about the site? That's a good question. I think the answer, again, is to look at other mediums. A magazine would not be launched by a major publishing company today without the investment of millions and millions of dollars to promote the existence of that magazine. Why? The newsstand is a very crowded place, ten thousand-plus publications out there. It's difficult to get shelf space, it's difficult to even get a newsstand to carry your publication. So you have to spend money on the promotion and the brand awareness for that publication.

Well, guess what? The Internet is a very crowded place. It's difficult to get shelf space; in fact it's impossible on the Internet. You have to be thinking in the same terms. You must promote that you exist. Again, you build it, they may come, they may not; that's quite a chance to take if you don't do any promotion for a new Web site.

Now, how do you promote? As I said before, with existing properties you're re-purposing a publication for the Net and you've got an easy promotion channel right there, the existing publication. That goes without being said. Then you have traditional means of doing it: PR, advertising, nothing new. I'm not going to spend time on that. However, that can be a tricky issue.

We lost a Web site that we put an advertisement in *TV Guide* for. Twenty-two million viewers. The site was very active, it was a short-term site, and it was up for two months. We put a survey in there where 2% of the audience said they heard about the site through *TV Guide*, and the other 98% was word of mouth — they saw it listed on "What's Cool" or got an e-mail from a friend. Traditional advertising is important; which medium, where you place the ads, how you use it — that still remains to be seen what's effective. I think things like *TV Guide* will become more effective in years to come, but today I don't know if the *TV Guide* audience was the right audience to get a Web site sent to them.

Then [there's] the digital means. All too often I hear, "Oh, we're going to launch our site and put a link or get a whistle on *Yahoo*." That does not get you hits. You're deceiving yourself if you think you're going to be able to put information in the listing services, all the listing services — and there's lots of them — and expect that people are going to come to the site. Whenever people say that, we say "Okay, what do you think people are going to search on?" "New York, because we're doing a publication about New York." We go to *Yahoo* and punch in New York, and 350 Web sites come up, and we say that's what you're competing with. That's the corner newsstand.

So while listing services, the *Yahoos* of the world, are important and yes it should be there, they're not a way to drive traffic. They are there when people are specifically looking for a topic or specifically looking for your site and forgot the address.

Newsgroups and links. I have a friend who does another Web site downtown, and he's going to put a link in his site. Again, if you're taking this seriously, that's not the way to get traffic. It's just not going to generate that many people going to your site.

How [do you get traffic to your site]? Advertising and PR. In the digital world there are many sites right now which do attract a lot of traffic. They're expensive — I will not quote numbers — to get links in there. But that may be an effective way to generate interest.

PR. Well, there's PR in the print world and there's PR in the digital world. Getting listed in Netscape's "What's Cool," in a sense, is PR. You have to call up Netscape, send your e-mail and promote yourself to them. They don't accept everybody because obviously they get hundreds of e-mails a day asking to be listed there, but it is a very powerful way. It's a source of information, it's public relations that allows the consumer out there to know what's going on. And that's all I'm really going to say about those issues.

Here's the big question. How do we make money? There are three primary ways: sponsorships, subscriptions and what I'm calling "pay-per-view." I tried to come up with

something cutesy for that, but couldn't think of anything. Maybe we'll all come up with a better term. What I mean there is basically paying for specific content: you see that picture, you want it, you click on it and it costs you three bucks. Or you see that article, you read the synopsis, you want to download it: you click on it and it costs you eight bucks or whatever it may be.

The reality is that that aspect of generating revenue is, I think, the farthest behind from the other two. Until things like e-cash or other minor transaction systems come into play it's going to be tough to really collect revenue that way. Some companies, some sites are starting to do it, but I don't think that's going to be the main source for quite a while.

Subscriptions. That definitely is a source of revenue. Sites today are doing it, and there the issues are pretty cut-and-dried. What do we charge for the media, for the content people are getting? You've got to be honest with yourself. What is it worth? You will find out very quickly whether you picked the right number or you didn't. You can look at hits and see how many people are registering once they hit the site, and if they're not either the content stinks or it's too expensive. On the other hand, if you get a lot of hits and you've got a lot of registrations, up the price. It's like anything else, supply and demand and all that stuff.

What I'm going to concentrate on is sponsorships. We are in the United States here, we are Americans and thank God for advertising and all that, but that's where I believe the bulk of revenue — just like traditional mediums, just like print, television — the bulk of revenues can be derived out of that area. So let's spend a little bit more time on that.

The first thing for content providers out there [is that] you have to deal with the ad agencies. I don't want to offend anyone, but it's foolish not to. Yes, that slows down the sell cycle, yes you're dealing with organizations that in a lot of cases — and that's a gross generalization — but in a lot of cases just don't get it. However, if you start positioning yourself with their clients as having the capability to put on an interactive ad for that client, you're getting yourself into a dangerous area. We're speaking from some experience here.

Agencies do have value; they create the message for their clients. We get approached all the time for our publications by the clients who are actually saying "We think this is cool," or "Hey, this brings our audience, we want to put a spot in there." We say, "Great, who's your agency? Let's work with them." Because what's going to happen is that the client is going to start treating you like an ad agency. That's a very, very human resource-intensive process to create interactive ads. So my suggestion again is to try to work as much as possible with the agencies, whether the site exists for a potential sponsor or not.

One of the key things that is becoming apparent right now with sponsorships on the Net is that the concept of "put up a banner and people will click on it" is going away very quickly. I'll show you how quickly this is changing; six months ago that was the case. You threw up an icon, you threw up a GIF image or something, and if the pointer turned into a hand you were guaranteed a click. It was kind of neat to see "XYZ mega-corporation has a Web site on the Net so I want to see what they're talking about." Well, Web users are significantly more savvy today. They don't click. They don't click unless there is a reason to click. My message here is that when you're going after the sponsors and when you're working with the sponsors, you have to be as flexible as possible to try to figure out how to work that sponsor in with content. I'm not saying to jeopardize your content in any way; it can be something as simple as you have a travel section in your publication and it's sponsored by an airline.

That's a pretty cut-and-dried relationship, and there's a reason you're bringing an audience that is interested in travel. Well, the airline makes sense. Again, this is nothing new, this is what's been going on in the print world for a long time, and we're accelerating in that relationship. But you have to be thinking in those terms.

The other thing I have up there is the "site within a site" philosophy. When you're talking to potential sponsors, start talking to them about creating specific content for their site

within your site. Where it physically exists doesn't matter, of course — this is the Net. The message here is, why would a sponsor have a position within a publication that reaches one audience and a banner and a publication that reaches a completely different audience? Even though they might be going after both of those audiences, and it comes to the same Home Page as when you click there — you've got somebody there, you've got that 18 to 34 demographic, you've got women who are on the Net or whoever that content is targeting; build something specific within the site that draws them in even deeper and then maybe send them off if you need to do that.

Again, as content providers you have to be very creative in how the sponsorships are linking within your site. It is a short-term approach just to say, "We got a banner in there and yeah, we can put their icon up with a link for X-thousands a month," because what's going to happen is that you're going to put it up there and no ones going to click, and they're going to say you didn't get the hits you promised us. So that's a no-win situation.

Finally, as content providers our responsibility here is to be able to demonstrate that we're bringing an audience to our content. Again, like any other medium, there are two ways of doing that. There's hits, and they're showing demographic information. Again, everyone is saying that hits mean nothing, hits are worthless. That's bull. Hits do mean something. The technology is in place to measure specifically what people are doing on your site. That's a very powerful thing and I'll argue with anyone in this room that it's a lot more accurate way of measuring how successful content is than any other medium.

You're talking about mediums out there — going back to Nielsen — that measure 2,000 families, 10,000 families for television ratings, and that's supposed to represent 90 million people. Well, with your content you can tell specifically where people are going and what they are doing on the Net. That exists today; it's easily done.

What does a hit mean? That's the big issue. We cannot be focusing, as content providers, on how many hits, but rather what the hits mean. There is a lot of information that can be extrapolated from a million hits per week. You combine it with other information; there's a million hits per week, and that week we had 50,000 unique domains accessing the site. Now you can start to figure out people.

It's still a rough estimate, but you can start to figure out the number of people that you're talking about. The problem is that people say, "Well, a million hits probably represents a lot less people." That's probably true, but it works the other way. There are a lot of on-line services which are becoming much more popular ways of accessing Web sites that cache all their information at the service location, which greatly decreases the amount of hits you're getting.

The bottom line is that we have a story to start telling now about what hits mean, and what I'd like to propose for those content providers in the audience is that I think we have to take the initiative. We have to be proactive and not sit back and wait for a third-party counting service to come in and say "Well, we'll be the third-party verification for you, but say, listen, this environment, this network, the technology is built on open systems and standards." Let's create an open standard, a way of measuring what hits me.

It's not that tough to do. And I would like to offer, pro bono, the services of my company to help make that happen. Right now the technology is out there. The counting software that my company uses for our sites — unless I'm missing something, and I may be — is as technically advanced as any third-party counting software out there. Why do I want to pay a third party just to say, "Yep, we looked at your reports and they're valid." Let's come to an agreement on how we can open up this for the entire industry to make it a fair and equal way of measuring activity.

[They talk about] demographics. "You can't tell whose on the Net, you can't tell whose looking at the site." Of course you can. It's the same way that everyone else does it — you have to poll your audience. You have to ask the questions. You can get some general demographic information from a hit, from log reports, but within our publications we ask the questions. What is your income? And people actually respond, probably as effectively as they would respond in other mediums.

When you fill out the questionnaire for *Vogue* magazine or whatever, we show those demographics to our advertisers. It's powerful stuff — and by the way, the survey information that we're getting back is from several thousand people every month. We're talking about a lot of people. They are pretty statistically accurate. So use that. Ask the questions.

The question then is, how do you get people to fill out the information? People don't like filling out forms, and you have to get creative there as well. *Word*, for example. Anyone can read *Word*, anyone can browse — or lurk, if you will — the publication. But if you want to become a member of the community — that's kind of a happy term for interacting with other people — then we ask you to register.

We're not asking for names, because we're not selling a list. But we are asking for demographic information. And you know what? We're honest with people. We say we need information about you for two reasons: number one, it allows us to understand who our audience is better; number two, we have sponsors here, and sponsors want to know who our audience is as well. People don't seem to mind when you're honest with them. Just saying, "Fill this out and you'll get a T-shirt" — I don't know how effective that is anymore. The message there is don't be afraid to ask the question, because you're going to have to do it eventually anyway.

This is more targeted at members of the advertising community, because the success of the Net is going to be so heavily leveraged by the relationship between content and sponsorship. Whether you like it or not, that's the way it is. I just talked about some of the responsibilities of content providers to show the audience; now I want to talk about some of the responsibilities, if I may, for the advertising community.

First of a few things here — don't fear the medium. Yes, there's a lot more accountability in this medium. You can tell very quickly, in general terms, how effective your creative is. I'm talking from an agency perspective now. If someone looks at the first two pages and doesn't get beyond the next one, that might say something about your creative.

So there is significant accountability, but you have to turn that into a positive. Now, there's significantly more value-add for agencies out there. Number two: the hype. It's okay to [do that]. We all participate in that game a bit, but every week we read about the new Director of Interactive for major agency XYZ, and then we go meet with them and this guy or gal doesn't even have a PC, and the interactive department consists of two people, the secretary and the individual, and sometimes it never seems to be there. And that's reality. That's happened several times and it amazes me, again, how these are major agencies who are trying to position themselves as players in the interactive game, and they're just not taking it seriously. And the reality is that even some of the sites launched supposedly by those agencies are getting built by interactive production houses anyway, with very little input from the agencies. So that has to stop.

Stop the knee-jerk reaction to your client who's saying "We need to be on the Net," because the reality is that the clients are driving this. "We have to have a Web site, so build one for us because you're an agency," and they say "Okay." The next thing you know you have the bicycle tire site, the toothpaste site, you have the chewing gum site and you have the contact lens solution site and guys, it doesn't work that way. I mean, it doesn't work in print that way; you're not going to have the Contact Lens Solution Magazine. You're not going to

have the Chewing Gum Magazine most likely. However, your gum site should exist within that magazine that reaches that young audience that you're trying to reach. This is common sense, basic media and promotion here.

It's basic sponsorship. So stop charging clients the hundreds of thousands or dollars for ineffective sites when you can pay a content provider hundreds of thousands of dollars and make it more effective.

The last couple things I have here... [The first is] strategy. Actually, creative strategy. Every interactive group — not every interactive group, but again, I'm speaking in generalizations and I don't mean to offend — but so many of the agencies' interactive groups are just orphaned children. They are out there and I say "Well, are you working with the media planner for this client on this site that you're building?" No. What do you mean, no? I mean, the campaign has to self-promote, it has to cross-promote here. How can it be so? They just don't do it. That's bad strategy.

[Tape change]

Daniel Pelson: ...incorporate interactive into their overall media strategy for their clients. It's here, it's staying and it's not going away so you might as well do it sooner than later.

Finally, I have the user technology. Again, just like when you're working with contributors to create the content as an advertising agency, once again — I've used this word many times — I'm amazed at how many advertising agencies don't have Internet access, how many advertising agencies have a bunch of stand-alone PCs on the desks and they're trying to create interactive presence for their clients. It's impossible. You just can't do it. You have to understand the technology and use it yourself before you can promote it to someone else.

To basically conclude, we all have a lot of responsibilities out there to make this work — and it's going to work, so I guess it's not so much making sure that we take the responsibility, but who's going to be responsible here.

Content providers have to be responsible for showing the audience. They have to be responsible for taking the medium seriously. They have to be responsible for investing in this technology and investing the time and effort making the content consumer-grade content.

[For the] advertising community, same thing. Basic. Take it seriously, treat it like other mediums, bring it into the house, accept it and raise it, work with us and we'll work with you to mutually beneficial relationship. But the bottom line is that until it's taken seriously enough with the investment, you're not going to get anywhere with it, as a content provider or an ad agency. And that's it. Any questions?

M: [inaudible]

Daniel Pelson: The question is two things. Number one, I'm not saying we move away from the model of sponsorship necessarily; what I'm saying is that we move away from the model of how we use content and sponsors together in the medium. Sponsors are going to have to start thinking about and advertisers are going to have to start thinking about building services within sites, ones built farther beyond the simple "Here's our logo, click on it and you can find out all the ATM locations we have in the city." Build services. Instead of clicking on that and getting ATM locations, click on that and start dealing directly through Internet relay chat with a customer service person right there. Use the medium correctly and create services. That's what going to drive business.

The question about the *New York Times* putting up the *New York Times* for a buck versus buying it for four bucks, I agree with you and I think *New York Times* is probably going to figure out how they're using the medium. And that's my message there.

I'm putting words in their mouth, so I may be wrong, but I believe they're using the medium to help promote sales of the *New York Times*. So you do spend four bucks; but like you just said, why would I do that? *Wall Street Journal* is the same way. I mean, I've got it all there. Just stop buying the *Journal*. Yes?

W: [inaudible]

Daniel Pelson: Right. As a community member we don't call it that because it would turn people off, but when they do register they can interact with the writers and with other *Word* viewers. So basically they're linked into bulletin boards, they're linked to chat sessions, they're linked into special areas that will allow them to interact. The philosophy there is that if you just want to read what's going on and not participate, fine. We don't need to know anything about you. But if you're a participant, if you want to talk to the author with the bulletin board at the end of the story — and virtually every story we put up has a bulletin board at the end of it — then we're going to ask for some information about you. We want to know who is interacting.

W: [inaudible]

Daniel Pelson: We're estimating about 10% to 15% right now. We have to do a better job with the technology, because we're talking about lots of different browsers out there. I think that's one of the reasons that that's been lower than we want, but that's still several thousands and thousands of people. Question over there?

M: [inaudible]

Daniel Pelson: The question is accounting data, how much is automatic, how much is user-provided? The hit reports, the log files that we generate are automatic. Every morning I come to work, go into a password-protected area of our site and see how many people read *Word* the night before and where they came from, and that provides information.

Let's see if I can hit everything here. It provides number of total hits and the number of domains that originated from; it provides the country of origin, and if it's in the United States, it breaks it down by .com, .gov, .org or .edu; it provides a number of some things a little bit more mundane but can be considered interesting to some of us.

How much data was actually transferred? We're getting close to a hundred gigabytes served. Kind of like McDonald's — we'll be there in about a month or two. It's a lot of content. Think about it. That's a lot of stuff.

And then it gets down to which directories have been accessed the most and then down to specific pages. So that's the kind of information that comes automatic to us.

The demographic information where we breakdown male, female, income, occupation, zip code, that kind of stuff, age — I think we ask a few more things there — that's also automatically tabulated based on forms and CGI, but that is the information that we ask for. So when they click on the bulletin board, if it registered it asks them for a password; if it's not then it sends them to the registration screen. It's automatic, by the way. They put in their information and they can start playing. Yes?

M: [inaudible]

Daniel Pelson: What I was referring to was not through the on-line services. I kind of melted and blurred two points together; I apologize about that.

My point was that from the Internet you can gather hits and look at domains served and then start to extrapolate information, because the domain is a unique IP address, basically. Now, the problem with that is a company like — this might be a bad example — but Sun Microsystems might have 15,000 Web surfers on their network, but be coming through one domain name. So it's hard to really get a detailed number, but the message there is you can start to extrapolate. If you get a million hits and five domains, you need domains. You know that you're not reaching too many people. You get a million hits and 90,000 or 100,000 unique domains, you can start to extrapolate that you are reaching more people.

My message about AOL was that it's the same situation as Sun. AOL has two million potential, two million-plus Web surfers on their network, but they're all coming through the same domain name so that shows up as one click in the 90,000 domains, and that [one click] can represent two million people. And we're also seeing it because we gauge what kind of browser people are using automatically, by the way. We ask that question. Most people don't even seem to know, but we also gauge it automatically based on what directory we seed them to transparently, and we're getting many more hits from alternative browsers — which means on-line services to us. That's an important issue.

And by the way, the one last point about that is that you can beat up the on-line services to tell them not to cache your content. They're getting hundreds of requests a day, so they're going to change policy pretty soon because they just can't handle the complaints from the content providers. The problem with that, though, is that it's pretty slow to access fresh content via the on-line services because they're dealing with so many users out there. Question from the corner?

M: [inaudible]

Daniel Pelson: Sure. Before I do that, let me see if there are any other questions. I'll be happy to. Two more questions? Go ahead.

M: [inaudible]

Daniel Pelson: Which files? Is there any further interpretive software for the log files, that was the question.

The software that we're using is a combination of stuff that we basically found on the Net that's good counting software, and code that we're written ourselves. So yes, we use additional interpretive software, but we do more analysis than most of the stuff that's out there. It's not that complex because there's a limited amount of information coming from log files. Again, what I was proposing is that number one, [inaudible] gets together and maybe builds on that software and creates some standard way of analyzing log files; and number two, we open it up, we just make it free and everybody uses it. If your sponsor wants to see your hits, because they're demanding it, here's the password. I'm not saying we share our information with everyone... Maybe that's the way to go too, that you open up that kind of information to the sponsor community.

M: [inaudible]

Daniel Pelson: Let me try to repeat the question. There's a medical journal that won't publish anything in print that was previously available on the Net, and there's economic journals I guess you're working with that may be considering the same thing.

I think that's probably a legal copyright issue, and in fact I think one of the presenters today is from a law firm. You should probably sit in on that and ask that question. My opinion is that it sounds like a little bit of a fear factor. The bottom line is that every one of our writers and contributors and artists — and audio people, for that matter — sign a contract with us giving us exclusive rights to their work for a limited period, and as far as we're concerned it could go anywhere else they want. Whether a print publication decides to use that material or not because it was on the Net, that's kind of unusual, I think. It sounds like more of a legal issue and I'm sorry I don't have a perfect answer for you there. One more.

M: [inaudible]

Daniel Pelson: It's a good question. We ask ourselves that every day. The question was [about how] we spend a lot of time doing content for different browsers, and is it worth it? We're constantly evaluating that. Today I believe the answer is yes. The primary browser out there is unquestionably — and this is not a sales pitch — but is unquestionably Netscape. They're giving it away for free. It's hard to compete with that, and it's feature-rich, no question about it. It allows us to do some neat things too, so we like that.

But as I just said, the on-line services are becoming much more proactive in getting people to surf the Net, because they're getting that billing time. And they have their own browsers. The good news is that most of the on-line services now allow you to use the Netscape on the front-end, but people aren't technically savvy enough to be able to do it themselves. So today we're getting a lot of hits from non-Netscape browsers and we specifically measure that. You can specifically tell how many hits were getting from non-Netscape browsers, and that gives us enough information to say, "Yeah, it's worth maintaining a couple versions." When we see that hit count go down on the non-Netscape browsers or move to another browser, we're going to make decisions on a continual basis. And the aspect of *Java* is another thing. The bottom line is that this is, again, consumer-driven content. We don't want people to see broken images on their Page, so we have to maintain the version. Yes?

M: [inaudible]

Daniel Pelson: Yeah, correct me if I'm wrong, but I'm pretty sure Netscape caches in the disk until you clear it. Not on a Mac though, right? It does it on a Mac, too? Yeah, it'll hold it forever until you run out of disk space, I assume. Is that right? Want to take a vote? Yes. That's right. You might have your browser set to empty your cache every time you log out; we'll have one of our engineers take a look for you.

The next four browsers really don't have specifics, because all we're looking for is Netscape and non-Netscape. It would be pretty easy to tell what they were if we wanted that information, but as far as we're concerned it's the Netscape version, and then the non-Netscape version is lowest common denominator. And if you look at *Word* from an AOL browser or a SPRY browser or a CompuServe browser, it's going to look the same amongst those three. If you look at it from a Netscape browser, all are completely different.

M: [inaudible]

Daniel Pelson: Again, what we do is Netscape 1.1 or above, so anything that's non-Netscape 1.1, including Netscape 1.0, falls into the non-Netscape category. So again, we don't count it specifically, it falls into another category. It wouldn't be tough to do if we wanted to, but it's not important to us at this time. Any other questions? One more.

M: [inaudible]

Daniel Pelson: If you're talking about from a communication speed standpoint, there's nothing that we can do. As a content provider, that's a good issue. I mean, that's why they have to focus on the distribution speed of the content itself, because once it gets to a network access point where AOL hooks into IconNet, which carries our traffic, it's in AOL's hands. So if their network is down, for example, then AOL users can't reach our content. That's the unfortunate fact of life here. Yes?

M: [inaudible]

Daniel Pelson: A lot of cases we eliminate it, we take it out completely. That's lowest common denominator for us in some cases, push/pulls, things like that. Server push, we pull out completely because it just doesn't work in a lot of those environments. Specifically, there's probably less than 30 things that we do and again, I invite you to stop by the Icon booth and maybe sit down with one of our engineers to go over that.

Someone wanted to see the difference here. The thing I was just trying to show here was not that this is poor design, I'm trying to show philosophy of what's going on on the Net. All of these, these are major media companies, in some cases partners of ours, so I don't want to upset anybody; but the message here is that let's say there's a picture of Princess Diana at Time Warner; there's a picture of Diana on *People* magazine, and the bottom line is I would guess, though I may be wrong, that this is to promote *People* magazine. I don't believe, in my humble opinion, that's the best most effective way to use the medium. That's what I'm trying to show here.

Something that you should do if you haven't done this already is start getting more into this and start surfing this, and when you start getting to the actual content you're going to see even more dramatic differences, pages of black text on the gray background versus true multimedia experience that transports the viewer through the content — and that's what we're trying to do, not re-purpose text for this medium and fill in the picture because we can. It's all very intuitive interface.

M: [inaudible]

Daniel Pelson: Warner.

M: [inaudible]

Daniel Pelson: Audio logo.

M: [inaudible]

Daniel Pelson: We're a heavy user of one particular technology right now called "real audio," from Progressive Networks. Every story we put up has original music or sound with it. Some are very short. If you click on one of these things — and this probably doesn't have real audio

playing — this is a talking painting. There's original artwork with original spoken word, poetry with it. If you click on this you could get three minutes of spoken words, but you go to some other stories, like the piece on tropical Morocco, [and it has] has 20 minutes of Moroccan beat with it. Of course, it starts playing automatically so people don't have to worry about the download time — that's the beauty of streaming technology.

[Inaudible] with audio is been pushing it, some of our users will tell us maybe too hard, but we've been pushing that kind of technology within the site, and the good news, once again, is that there's new technologies coming that are going to make it a lot easier.

Jane Dysart: Thanks Dan, and I would urge you all to visit him at booth 444 in the exhibit. Now is a short break, and our next session will be at 11:30 in this room, "Large-Scale Information Retrieval and Dissemination on the Internet."

INTERNET PUBLISHING LARGE-SCALE INFORMATION RETRIEVAL AND DISSEMINATION ON THE INTERNET

MODERATOR

Jane Dysart
Partner, Dysart & Jones Associates

SPEAKER

Bill Phelan
Director, Internet Product Marketing, Dataware Technologies

Jane Dysart: Okay, we're ready to go on the second session of the Internet Publishing track. We have Bill Phelan, a change from the program, who's going to talk about large-scale information retrieval and dissemination on the Internet. Bill is the director of Internet Product Marketing with Dataware Technologies. Dataware is a company that deals with solutions which enable customers to create, manage and distribute electronic information, whether it's on CD, on-line or over the Internet. So, I will turn it over to you, Bill.

Bill Phelan: Thank you. Good morning, everybody. A couple of quick questions before we get started... With the focus of today's presentation on large-scale Internet publishing, I've wondered if maybe we can get started a little bit by asking a couple of questions.

How many people here in the room have Web sites that have over 100 pages of information available to use today? I'd estimate that at about a third. Anybody in the room have over a 1,000 pages of information? And about half that again. How many people here think that as their investment in the WorldWide Web increases they will start to reach those limits of numbers of pages or documents on the Web? Something we're seeing increasingly is that a lot of people are struggling with managing large volumes of content as they take either historical bodies of information or large collections of internal documents and try to put those up on the Web so that a lot of users can access it in a secure, yet easy way.

Today what we're going to do is walk through a quick review of the current state of Web publishing. [To begin, I'd like to] define a few terms to make sure we're all on the same sheet of music, and talk about the climate a little bit, things like what "volume" means today on the Internet, and on the Web specifically. Then I'll change quickly to talk about large-scale Web publishing issues.

There are a number of barriers, if you will. It really makes publishing hundreds of thousands of pieces of information on the Web quite difficult today — or at least not as easy as it is through other mediums. We'll talk about some large-scale Web publishing requirements that I think you should probably consider as you put your strategy together for how you want to deliver information on the Web.

First, before I get too much into the presentation, what do we mean by large-scale publishing?

The first thing I wanted to touch on is what we talk about when we talk about publishing in general. Publishing is enhancing information and integrating various ways of looking at that information. On the left-hand side is the value chain, how you think about data and how you want to organize it and present it to users.

You have disparate information, information from various sources in a variety of formats; as we start to add value, and look to publish that and make it accessible to users in a more easy to understand and accessible manner, we start to categorize that information. We start to screen information, get rid of redundancy perhaps, and rank it according to a certain

scale as to whether it's appropriate for a particular group of users, or perhaps should not be seen by other groups of users.

As we continue to add value to that information perhaps we start to add our own interpretations — editorial content like, “Okay, here is my view of this particular piece of data or collection of data.” We try to profile that information, then group it into useful bodies and make that actionable.

[And finally], we put together a complete solution so that users may quickly find what they're looking for and draw conclusions from the data.

At each step in the value chain, as people organize and make more accessible these bodies of information, there are chances to add value for internal sites that may be simply screening, getting rid of redundancy, or providing a secure, predictable access to that information. On the way over to the right-hand side of this screen, making it actionable requires a far more significant investment. How much time you spend and how you organize your information with respect to the Web or any other electronic publishing medium really depends on what your goals are. Another way to think about the publishing problem, whether it be the Web or any other medium, is to consider what we have constructed here: [an illustration of] a “publishing quality” pyramid.

At the bottom of the pyramid is kind of the state of the general WorldWide Web today, where there is browsing technology and where the browsers are separate from the information itself. There's not a lot of inter-relationship between what the user sees and the presentation in the browser; the browser is not aware of the data itself, but rather simply just puts it up for the user to view. You can not [assign] value on the data side if you're publishing.

But what we're looking for is a better level of abstraction, to build more intelligence so that user interfaces can help users quickly identify what they're looking for and not have to make the investment in changing all of the data in order to accomplish that. [We want to go] a level above the simple browsing metaphor, the surfing metaphor of looking around at these bodies of information in a more narrow niche of application.

[We need] a tighter integration between the information that you're looking at and the software solution through which you view through, and query in, and locate the information that's interesting. From a commercial perspective, commercial publishers get that stuff further. They not only more tightly integrate the software and the information but they do so in a commercial manner to produce titles for sale. And again, where you make your investment and how you organize your information, how you collect that information and present it to your users through your Web site really depends on what your goals are.

Switching this general discussion of how to organize and present and categorize information, or add value to information or add value to data to really make it usable — that's what people are doing on the Web today with respect to large-scale publishing. They're putting up large volumes of information and making it quickly accessible to a particular group of users.

The category of that is a lot of Home Pages, smaller groups of documents where there is a lot of marketing-type literature typically classified as establishing a Web presence. [There's been] a mad rush of: “We've got to get [our] organization up on the Web and at least present some collection of information which describes what our mission is, who we are, how to get in touch with us and what types of products and services we sell.”

Some common criticisms are that there's a whole lot of sex and sizzle but perhaps not as much content, and not as much detailed information on a lot of Web sites that people are looking for. But, as we all know, that's rapidly changing as the volume of information on the Web and the collections of information on a particular subject continue to increase rapidly.

Just to put things in perspective, how much content, how much volume of information is on the Web today? Using some rough estimates provided through a variety of sources that I'll

make sure to give reference to, there is roughly 8.7, somewhere between eight and nine million pages of information on the Web today. That has come through a variety of research, as well as through some of the on-line indexing sources such as *WebCrawler* and *Lycos* and *Yahoo*.

Lycos went one step deeper into their research, and through their indexing has determined that each page of information on the Web contains roughly 8,000 bytes of text. And there are roughly — this is probably in order of magnitude, our [source material] is a month and a half old — but roughly 41,000 servers on the Web. That is outside the buyer service. There's probably — in order of magnitude — a greater number of servers [if you include the ones] inside the companies and inside the corporations, the ones that the people are using to disseminate bodies of information to internal users. This number states the number outside the firewalls and on the public WorldWide Web.

Doing some rough calculations here, it results in the following numbers: as of a month and a half ago, the Web was roughly 65 gigabytes in size. The reason we went through the trouble of coming up with this estimate is because in all essence that's a lot of information that's simply not being — [there are] huge amounts of information that a lot of people who are responsible for publishing information for internal use or for commercial use are used to dealing with. We hear much more of people struggling to present hundreds of megabytes or multiple gigabytes of information.

So the Web, in terms of the publishing of a large volume of information in one site, really hasn't hit that issue yet. With the average data per server roughly one and a half megabytes, if my division is [correct] — but that's rapidly changing. Commercial publishers, through a series of advertising-supported services and using fee-based services, are starting to put up their historical repository of information, whether that's, for example, archival access to large bodies of research or access to the latest and greatest news information from particular periodical publishers.

A different set of information is being published internally to allow corporations to more easily communicate among offices and to establish a better rapport between [themselves and] their customers. And then governments and universities are publishing or making accessible a lot of large bodies of content through the WorldWide Web as well. So we're seeing not just more sites on the Web, but a lot more content, and that's where the issue of large-scale publishing starts to come into play.

What issues are facing large-scale publishers? For people who want to put large bodies of information up, well, there's a series of data issues first. Looking to put up your large collection of data means that you have to look in a lot of different places, whether that's in information stored in different document formats — that represents a challenge — or whether the issue is that you're trying to put information stored in other databases where there are a number of different format issues you have to struggle with. Converting all of your data or all of your document information or collections of data into HTML really isn't a practical step for most people. So how do you manage, or how do you publish information in a variety of legacy formats? That's data issue number one.

Number two is how do you manage the volume, the huge numbers of documents, the huge numbers of records, with today's tools? The size of the documents becomes an issue. A lot of solutions available on the Web — and we'll categorize those in just a minute — have a problem when you start dealing with 50, 60, 70 megabytes worth of information. The solutions simply don't scale.

So then there's the issues of what format the content is stored in, the volume of data that you have to be able to manage, and thirdly, it's finding the right information. But once you have this information available, how do you make it easy for your users to search and retrieve

that data? How do you make an intuitive solution to let people automatically locate the information that they are interested in?

One recommendation when looking at a Web publishing exercise is that you really need to separate the information server concept from your Web server. A lot of Web server vendors have great tools for connecting individual documents and allowing users to gain access to individual documents. The *Netscape*-enhanced and *Spyglass*-enhanced ones do a great job of letting the user click on a link and download a particular document, but they don't really address the issue of storage for large volumes of information. Most Web servers rely on the machine, the file system and the operating environment in which all of those documents are stored to help address some of these problems. As you start to increase the volume, as you start to increase the audience that's going to access that information, you have security concerns and performance concerns and management concerns. So separate out how you want to manage your information and deliver that information from actually just providing Internet access through data.

A second class of issues are infrastructure issues and lots of network bandwidth problems. We've all experienced different latency problems when you're surfing around the Web. That really represents a big challenge for people used to different types or user-friendly types of interfaces to data. To give you an example: if I want to present a thousand documents with 20, 30 or 40 specific categories, how do you let users quickly browse through that category? Well, maybe I'd pop up a list and allow the user to scroll through — and that's a solvable problem today.

As the categories start to increase into the hundreds or perhaps thousands of different categories on the Web, expecting to be able to download all that information to a browser and then scroll through it simply isn't cost-effective or time-effective. It just takes too long to download large lists of things for users to browse through; so there's a network bandwidth problem that is part of the issue.

The other issue — I actually skipped a point — is lack of client site intelligence. Really, the client doesn't know, as we've pointed out before, anything about the structure of the data. The way people access that data is simply by providing a consistent front-end to all varieties of information; so if we could start to add more client site intelligence so that it knew what types of data it was looking for or at, you could start to address some of these usability issues and some of these presentation issues.

I skipped over an important point, and that is server site scalability. As the amount of information increases, as the number of people accessing the information increases, a lot of customers that we've spoken to are starting to run into bottlenecks. As I went from 20 users simultaneously accessing a body of data to 100 users or 200 users, I started to run into bottlenecks in my Web server and bottlenecks in my file-indexing software. So the server site scalability issue has to be one to be addressed as the volume of data you're publishing increases.

The last point is one I've seen discussed in several venues, and that is "stateless" versus [inaudible]. Does this mean anything to people in the room? How many people understand the concept of stateless versus [inaudible]? The Web today is inherently a stateless environment; and what I mean by that is that every time a user issues a query or clicks on a link to a particular piece of information, a connection is established on the server, and the information is then gathered and downloaded to the user and then the connection is dropped. So the server has to go off on a request-by-request basis and do some work and deliver things, and then it loses all knowledge about what the user is doing or who visited the site.

So every time I, for example, go to *Pathfinder*, the Time Warner site, and say I'm interested in this particular news article, I click on the new article and get that piece of data; but

at the point after I got my document *Pathfinder* no longer knows what context or what type of information I'm looking at. If I wanted to find related information, as a user I'd have to go through the steps again and the server would have to go through the same amount of work. There isn't any way to effectively capture knowledge about users and automatically use what they've already done to reduce the overhead on the server side and increase your performance.

So [let's say that, as a server], I get a request and I get a series of documents, and I know what collection of documents that the user has asked for; when the user says, "I want these five documents out of that list of a hundred," I don't have to go and perform the entire query again in order to find out which five the user was interested in.

That kind of wasteful overhead, that stateless connection, is one of the things that will start to bottleneck or present you with a performance problem as the number of users accessing your site and the volume of data that you're giving them access to increases, because there's a lot of redundant work that goes on every time a user asks a server for a piece of information. And all context is basically lost in a stateless environment that the Web has today.

So what requirements should you think about when you're talking or considering putting large bodies of information available on the Web? We're going to run through each of these in detail. What we'll talk about, in terms of production publishing needs, are the needs for a sophisticated database and for searching. It's the idea of value-added presentation, taking it back to the early part of the slides where we talked about adding value to your information and categorizing it better, presenting a clear view to users so that they have clear access and faster access.

As the volume increases there are security concerns. Perhaps not all users should have access to all data. If you're considering a commercial publishing exercise you want to be able to meter that access and perhaps have an accounting interface so you can charge for access to the data. We talked about document formats; one requirement should be to support existing document formats so that you don't have to re-publish everything, if you will, into HTML. You need to consider publishing performance — how optimized is the solution for delivering large volumes of data in a query and retrieval type of environment — and then think about the standards on which the solution you are evaluating is built.

Let's quickly investigate these requirements on a one-by-one basis. When we talk about sophisticated database and searching, lots of people have ways to publish — or index, if you will — content for the Internet today. Some people put in a file-indexing type of product, and basically you can point at directories on your machine that contain your documents and it will extract the data and make it available to users. That's one solution.

However, as you start to increase the number of users and perhaps run into issues of security, think about the scalability concerns there, and also the security concerns. You don't want everyone to have access to the same body of data; you want to have a repository in which you can control who has access to what. A lot of solutions — also, again, on the full text side — only allow full-text searching. "Find me all documents that contain this particular string: Bill Phelan at Dataware." That doesn't do all that much when the user is really interested in only documents that contain that piece of information in a particular section of the document.

Whatever solution you're looking at should support both field searches — "Only show me documents with Mecklermedia in the title, only show me documents with Albert Einstein as one of the site references to that particular set of material," — as well as full text. "Show me all documents that contain Mecklermedia and Albert Einstein," as an example. [You need] extensive query flexibility.

Again, on a sophisticated database and searching side, look to the point of providing users better access and better searching mechanisms to quickly narrow the sets of documents they're interested in. Here are some examples — and we'll talk about them in a bit of detail — but basically, if I know what I'm looking for, they don't make me have to understand a particular query syntax. [You can use it to] automatically, for example, give you the option of looking at a magazine — and magazines, plural — or automatically derive from the query that not only am I interested in magazines but perhaps periodical publications too, which is a synonym for that same term.

Don't make me learn a somewhat archaic query language; let me enter the queries in a natural language format and help me understand the results as they come back. And then the final requirement here is multi-lingual support. If you're considering distributing information outside the borders or [outside] North America, make sure that you're user interfaces and the documents that you put into your databases can be in different languages.

We ran into a customer who made an initial Web investment and put up 50 or 60 megabytes of data, then went to distribute that solution throughout their organization only to find out that their database solution, their information server solution, only supported English-derived languages. It didn't support double byte characters, it didn't support some of the extended character sets of the European languages. So that's another thing to account for when you're looking to publish large volumes to a large audience. Separate how you organize and allow query access to the information that comes back to how you're going to present that information to the user.

What's the best, most effective way to put the user in touch with the data they are looking for? The first requirement to consider is off that subject a bit; it talks about making sure you can store documents of different formats in whatever information server solution you're looking at so that those are automatically converted to HTML. At least there is an initial conversion into the [inaudible] of the Web; you don't have to go and re-author all of your data.

We also ask you to consider different ways of presenting that information, like conditional layouts — hiding information and viewing information depending on what the user is, who they are, and where they're coming from; and highlighting information automatically, allowing configurable controls so that perhaps every time I search through a large body of data I can give the user some feedback. How many documents are left in my query as I'm looking through it? How many bytes per document are there? The idea is [that we could] perhaps give different headers and footers to give users that information. Giving them an idea of where they are and where they've come from is important.

If you're considering commercial publishing, you also want to have control over the wrapper around the documents, [which are] the configurable headers and footers. Deliver different types of messages, whether that be on-line advertising or status and account information, depending on who the user is and where they're coming from.

Here is one representative list of how you can start to think about adding value to your data, some different metaphors you can use on the Web today — perhaps with some additional software — to let users understand the collection of information you're offering them and [let them] navigate it more quickly. Some sites have gone to a "Table of Contents" metaphor, or an "Index" metaphor — "Let me see all of the documents or give me a quick road map to the site or the collection of information available." Some people use hypertext links to navigate through collections a little bit more easily.

For example, not only do I want a link between documents on a particular subject — so that as I'm searching for Mecklermedia or Einstein references, maybe there's a dozen or two that have that type of information in it — then let me jump from document to document; don't make me jump back and forth between the Home Page or the query page and the next

document. Another metaphor that you can use is hypertext within documents. As the documents get larger and larger and you're delivering multiple pages, printed pieces of information on the Web, [you can] provide users a better metaphor to jump within that document, to jump from subsection into subsection or perhaps even from hit to hit. Let me jump from every reference to Albert Einstein. The rest of the document may or may not be important; let me jump from place to place to place, where the subject matter I'm interested in occurs, and therefore give me, the user, the ability to understand whether that document is relevant or not.

There are also other types of software and technologies that can help users find information more quickly. I can use dictionary as a metaphor: "Find all of the terms which mean publication or print media. Give me a thesaurus or natural language interface to allow me to navigate through and find relevant matter more quickly." Some of the information integration options are how you present the information a little bit more enticing. Does the solution you're looking at support in-line images, so I can look at a document and not just have the graphics separate from the content itself, but rather have them imbedded in the document, more true-to-life to a printed page? Maybe [you can] integrate multimedia capabilities, so if there are speaking audio portions of the document you can include those in-line in the information; then the user can not only can read the relevant pieces of data but also click on other types of images and multimedia support to give them a better idea of what's available to them.

In the last one, on the bottom of the screen here, we talk about feedback, and I think one of the most under-appreciated, value-added things you can get to add value to your information is to give users more feedback when they're looking for information and as they're reading large bodies of information. I really think that a Web browser is nothing more than a glorified 3270 mainframe terminal where, while there's certainly a lot of graphic content and interesting things to look at, the user is trying to enter information and get feedback about what they're looking at, enter a query and then receive some results.

It's really almost like a "block mode" environment. I'm entering in information — maybe the query elements, and maybe the questions I'm asking work or don't work depending on how I go about doing my work as a user — and finding ways, perhaps leveraging some of the desktop software that you already have, to give the user an affordance. More feedback, I think, is the next big step we can do, and offering users more effective access to large bodies of data.

A specific example: every time I enter in a state or a zip code, most client server packages and most other forms of electronic medium give me the option of at least automatically seeing what city and what state that zip code pertains to. On the Web today there is no such analogy; I need to enter in all of those elements separately. There is no smarts built into the browsers today. That kind of feedback can make the difference between a user finding what they're looking for quickly, or walking away in disgust because perhaps they gave the wrong zip code for a particular location and they're queries consistently come back with no data as it pertains to their answer. So how you're going to organize the results and how you're going to ask the user, and what kinds of metaphors and control you can give the user to provide quicker access — [those are important].

And finally, there's ways of navigating through the results that really can make an experience of accessing large bodies of data a much more intuitive and pleasurable and successful one for the user. Here's some of the things you can consider when taking the next step: from a production publishing perspective, again, as the volume of information increases and perhaps as the value of the information that you're looking to publish increases, you want to make sure that the solutions that you are considering give you the necessary security, metering and accounting interfaces. Make sure that you can control access at multiple levels. "I

want to be able to lock users out of accessing information at this site entirely," is one example, and something that Web servers do very well today.

I can also very easily lock out access to entire databases or an entire collection of documents. But that really puts the onus on the publisher to organize things on a database by database level; it's much easier if I can have all of my information in one place, and then control access and say that a particular user can only gain access to this subset of documents, or perhaps they can have access to all documents but can only see specific portions of those documents. Perhaps I want to provide all users access to title information and abstracts, but I don't want users to have access to the full contents of the documents unless they've registered on my site, perhaps registered and paid a subscription fee, or perhaps have an account that can be charged in order to gain access to that full content.

So consider those types of things when evaluating a query and retrieval solution, and make sure that the solution also outputs all of the transaction information that you as a business or you as a site are interested in tracking.

Make sure that they not only tell you who is accessing your information but what information they're accessing, when they access it, how much and how long; because those are all elements that can influence a decision about what data to put on in the future, what to charge for particular pieces of information if that's your interest, or where to add more editorial focus if you're inclined to increase the number of people accessing your site.

And lastly, if you're looking to charge for information, make sure that the solution supports a secure Web service, because without that secure browser and client there is no guarantee that people will take and pay for and use the transaction mechanisms out there.

[Keeping in mind all the] other standards is another requirement. Make sure that whatever decision you're making now doesn't lock you in to a particular platform or set of environments in the future. Make sure there is a support for the various flavors of HTML, and therefore for a variety of flavors of browsers, since you want to access the greatest audience. Make sure the Web server support is broad; don't just lock me into the freeware versions, but also [consider] the commercial versions. Make sure that I'm not forced into a particular platform decision. Make sure the support ability is there. And make sure that the vendor is tracking all of the emerging standards, because every week it seems there are changes taking place that affect the way different software works together and the way different publishing solutions can be integrated.

I invite you all to look at one possible solution to these large-scale publishing requirements on the Web. I work at Dataware Technologies, and last week we announced a product called *NetAnswer* which addresses all of the large-scale publishing requirements we just spoke of. We're at booth 212 on the floor, or come visit us at www.dataware.com. And I'm more than happy to take questions.

Jane Dysart: Thanks Bill. Are there questions?

M: [inaudible]

Bill Phelan: Yes. The question was, how do we see the role of *Java* in making the client side more intelligent? I think that people are focusing on *Java* because of the animation and the sex and sizzle, but *Java* has a lot of practical aspects to it as well. *Java* really allows you to put up these different kinds of controls and these different kinds of feedback mechanisms for the user. People shouldn't just look at *Java* and see a sexy, multimedia-type of solution but also something that lets users have that kind of immediate feedback when looking at a large volume of information.

M: [inaudible]

Bill Phelan: How important is the “contained search” content? Again, I’m research [oriented] [inaudible]. Well, that’s what we sell, so we think it’s very important. A lot of it comes down to the different classes; if you want to quickly put a volume of information up on the Web, and don’t have concerns about scalability and performance, there are file-indexing solutions that work very well. As the volume increases you really need to look at text databases, and the search engines on top of those, as the vehicle to deliver and manage and control access to large bodies of data. Does that answer your question?

M: [inaudible]

Bill Phelan: Obviously, a lot of what we spoke of are different ways of searching that information. Textual search is one of the ways, and natural language search is one of the ways allowing people to ask a question in a variety of ways and have other, underlying technologies support that text query. That’s a very important thing, because if people can’t find the information then your publishing it on the Web has no real value.

M: [inaudible]

Bill Phelan: Actually, they’re PDF files. For those of you who don’t know PDF, Adobe PDF stands for “portable document format,” and it’s a way that you can basically take content and present it and maintain it’s presentation. If you have watermarks in the background, column information, embedded graphics, etc., PDF is a very viable way to display that kind of rich publishing format. Embedded in PDF files is the full text of all of the documents, so we have technology that actually allows you to extract the text, make the full text searchable, and then when the user says that’s the information they’re interested in you can download the PDF or set of PDFs the user is interested in.

M: [inaudible]

Bill Phelan: You need software to make that search possible, that’s correct.

M: [inaudible]

Bill Phelan: The question was about what to do if you’re trying to publish across multiple mediums — the print medium specifically and also various on-line mediums, whether that be on the Web, an internal corporation network or on CD-ROM. The strategy Dataware has adopted is to always keep the original document in lock-step with a full text searchable solution. We’ll have links to the original document format, so you can do both full text query things — in order to locate the documents you’re interested in — and get the original representation of that document downloaded to you as well.

M: [inaudible]

Bill Phelan: That’s correct. So we have something that extracts information from a variety of document formats, pulls it in and puts it into our database, and then keeps the original documents and the searchable texts of those documents in lock-step with one another.

M: [inaudible]

Bill Phelan: How viable is it to produce a single database that contains both kinds — your documents for document management, as well as putting those documents available on-line? There's an open-ended question.

Realistically, we don't see a lot of people doing that today. There is the document production cycle that has a specific sets of issues associated with it. It's usually tracking it along the various stages of delivery and production and then, once that document is ready to be published — whether that be via print medium or electronically — taking it out of the internal document management system and placing it in a separate database is the strategy most of the customers we've worked with have taken. A lot of it has to do with concerns over security.

[Tape Change]

M: [inaudible]

Bill Phelan: Do I see the need for sessioning?

M: [inaudible]

Bill Phelan: The question is, as the Web is a stateless medium by default today, should that change in the future? We do see it changing, but in a couple of different ways. For people who want full-time access to data — in other words, if I'm a full-time researcher and I want to constantly access a particular set of data, I may want a proprietary interface, one that basically establishes the connection and keeps that connection because of the variety of benefits that I can give the user that way. I can make response times a lot faster and I can provide much more immediate feedback on things.

For general access to data, to a large audience, if I am not a dedicated user of a particular collection of documents but rather a casual surfer or a once a month user, perhaps I don't have that proprietary interface requirement; but there are still things you can do on the back end, staple types of things you can do on the server side so that even for those users who don't have a dedicated interface, they can get some of the staple benefits.

We can keep some intelligence around on the server side so that for the length of a person's sessions, for the next 20 minutes to an hour, we track everything they do and make sure that we re-use everything that they've done to help provide better performance and better access.

I think we're going to take one more question and then, unfortunately, we need to move on.

M: [inaudible]

Bill Phelan: Yes, you didn't, and there is a whole series of copyright and distribution issues as people gain public access to large bodies of information. [There's] lots of copying; as soon as it's on the Web, it's basically construed as free game, or it certainly has been to-date. There are services available on the Web — there's a company called Copyright Clearance Center and others — that are allowing corporations to at least do copyright look-ups to make sure that they have access and legal permission to copy certain pieces of information or can get that permission. Copyright Clearance Center is located in Cambridge, and they happen to use —

they're one of our early adopters of our *NetAnswer* software, so I'll give them a free plug. The point of the presentation today was not to talk and write about copyright.

Jane Dysart: But there are some other sessions later that will focus on that, and Bill will be here for another couple minutes for questions. Help me again to thank Bill.

INTERNET PUBLISHING INTERNET PRICING AND PRACTICE: AN OVERVIEW

SPEAKER

Patricia Sabosik

Editor-in-Chief, *The Whole Internet Catalogue* for GNN, America Online, Inc.

Patricia Sabosik: I'm Pat Sabosik, and I'm currently the Editor-in-Chief of the Whole Internet Catalogue for GNN, AOL's second brand-new Internet Service.

I was formerly vice president of Linked Media, AOL's Internet Services Division, and I am delighted to be here today to talk to you about pricing and practice and just what some of the trends are that we see going on in the Internet today. This will be an overview of a number of areas that I have identified where we actually have some numbers and some trends, and hopefully [have] some information to help you move forward. Since you're all at a show, incidentally, thank you all for coming after lunch. That's a big deal.

How many people actually are on the Internet today? Just about everybody. That's terrific. How many are on through an Internet access provider? Well, that's interesting. Less than half. How many are going on through one of the commercial on-line services? So the rest of you are educational institutions? Is that right? What am I leaving out? Companies. How many people are on through their corporation? Okay, there's the other third. Thank you. You know, you get into this consumer end of things and you forget — and I come from the academic side of things. So, here we go.

Today, at 10:30 this morning, America Online launched GNN, a separate Internet access service, and we're all pretty excited about that.

These are the areas we'll run through: the arena, what we see today in on-line and Internet services, and sources of revenue and costs.

Some of the things I'm going to outline can be a source of revenue if you're on one side of the fence, but could be a cost if you're on the other side. Take advertising; are you placing? Are you buying? What are some of the products that we see developing on the Internet that are a revenue base? And what are some of the marketing issues involved? Actually, with marketing, we'll talk about quite a bit in the front and then we'll end with some business models.

The interactive services today, for consumers and also for smaller businesses — larger corporations have been using the Internet for quite a while — is an emerging medium and an emerging market, and we look at interactive services as having these four components: the on-line environment, on-line services, the Internet, and CD-ROMs and multimedia, or the multimedia aspect of CD-ROMs and transaction services.

We see a shift from TV and cable to on-line services and the Internet. In a survey by both the Chiat Day Advertising Firm and Business Wire, a joint survey, 65% of teenagers spend more time on home computers than they do watching TV. We see a shift in the consumer end of the Internet market very similar to the cable model about ten years ago, with cable versus TV, where there were some "early adopters." We'll get into that; but we did see a movement away from one medium into another, and that's exactly what we're seeing today.

Without going into specific company figures, there are times during America Online's and CompuServe's and Prodigy's days where more people are signing on than are watching TV. What we're beginning to see is really the emerging of a new medium, and quite an interactive medium as opposed to the passive medium of TV. When we look at consumer adoption and where we are in the consumer end of on-line services in the Internet, these are pretty standard stages of adoption. There is the innovator, and they are price-resistant for the most part. It

maps out to a pretty standard Bell curve, where on the left we have “techno-lust” and on the right we have “technophobes.”

So we have innovators or early adopters, and these percentages, if you move from different marketing textbooks, will vary three to five percent, but not a lot. “Early majority” is the large half of the Bell curve and “late majority” is the second half of the Bell curve; and then we have the laggards, usually when a product is in a sunset phase of its cycle.

Where are we today? On-line services have passed the early adopter stage and we’re looking at a peak of about five million homes, and we’re moving into the early majority stage for on-line services. And that’s America Online, Prodigy, CompuServe, Delphi, Genie, and the Microsoft Network. And all those have Internet connectivity as well.

The mainstream is going to hit at about 35 million homes, and the projection we’re using is based on the number of households with PCs and modems. That figure varies from survey to survey, but there are some pretty standard [numbers]. I think that figure is around 90,000 households. And that would be about right; a little less than half would hit in the mainstream.

5.6 million homes subscribe to one of the big on-line services. They’re in the early adopter phase, and as you can see, crossing that line from five million now to close to six million into early adopters, 53% of homes in the U.S. have modems. This is from Intecho Corporation’s survey of on-line users. Intecho is a Norwalk, Connecticut market research firm. Some of their results were published in a few of the on-line and advertising newsletters and Robert Seidman’s on-line newsletter. If any of you get that, it’s really great just in terms of keeping a pulse on what’s going on in the on-line community. And Webster, for newsletters, and EduPage are good newsletters for Internet-based services.

Again, the Internet is moving. Now, the Internet — we’re not on [the subject of] on-line services anymore. We’re off of AOL and we’re on [to the subject of] TCP/IP. The Internet is moving into the early adopter stage. It’s now represented by fewer than 750,000 consumer households of the consumer market. The academic market probably has an 80% usage rate on the Internet, and that’s the arena that developed it.

The National Science Foundation, with funding from the government, subsidized the Internet backbone in the development of that for the last, almost twenty years, and then gradually withdrew the subsidy and pushed that whole network into essentially a business model in the commercial arena to pay for itself.

So academic research and business use are heavy users of the Internet today. Consumers are just beginning to get involved in that. And then we also see a shift; the biggest activity, the biggest area of action is a shift to consumer-based services on the Internet. On-line services integrated Web access in 1994 to grow the new medium and to capture the early adopter market. AOL announced our second brand today specifically to address the personal Internet market, not the business market. We do have a separate division called Enterprise Services that specifically addresses business-to-business Internet connectivity, but it’s without the programming and the advertising that we see in either GNN or AOL.

I’d like to talk a little bit about revenues and costs. There are four areas that we’re going to look at. Pricing [and] pricing access, advertising, memberships and subscriptions, and some transaction services.

Pricing access is the connectivity phase of the service where we see a trend. Our subscriptions are ranging now between \$5 and \$15 a month and \$2 an hour additional on the Internet side of the fence.

It’s slightly more costly in terms of machine overhead to manage the Internet connectivity than it is to manage the connectivity in an on-line service, and there’s two reasons for that. One is the technical infrastructure required, and the second is critical mass. The on-

line services, for the most part, are enjoying more than a million members, or at least a half-million members, so there's enough of a critical mass to spread overhead costs, to spread the fixed costs of just the computer center. There are just not that many Internet providers or Internet users hooking to on-line services. So, we have those two issues.

We also see a market push to lower prices to move this into the next stage of consumer adoption, and that happens as any new product runs through a product life cycle. The market pushes the cost down — if you're looking at a pyramid — so that we can reach the base of more users. When I did a talk on pricing six or seven months ago at Internet World in April, the subscription prices then were higher, with the average much higher than the \$5 to \$15 range. We were looking at the \$20 range plus \$2 an hour.

So the additional [hourly cost] factor has not dropped, but the threshold to get onto that service has actually dropped about \$5 and I think we're going to see more of that over time. These are just some general pricing [numbers] for the on-line services. CompuServe earlier this year dropped its price, which was a little bit higher threshold, to match America Online, so now they're about the same. The difference between the two services is that AOL is flat fee and CompuServe does have some content surcharge areas, so depending on what you want you can take the same ride for the same cost or you can pay a little more to get into certain other areas.

Prodigy has a slightly different rate, basically a dollar an hour plus about \$2 or \$2.50 an hour for additional [hours], plus content surcharge for some of those areas. The Microsoft Network is trying to drop the bar a little bit; it's \$4.95 a month for three hours plus \$1.95 for additional [hours], plus the content surcharge areas. And there are more of those in the Microsoft Network than there are in some of the other on-line services because of the way they've structured the relationships with publishers so that the publisher has a say in what the access fee will be to get their content.

[Let's talk about] Internet access providers. What we're seeing is the emergence of national Internet access providers as opposed to local Internet access providers. And here are three: GNN announced today, and their pricing is \$14.95 a month for 20 hours plus \$1.95 additional [per hour]. NETCOM is \$19.95 a month for 40 hours [plus] \$2.00 additional [per hour]. Non-prime time is free, and non-prime time is midnight to 9:00 a.m. And Sprite — which is a play on SPRY — [is] CompuServe's Internet access feature. It's a cute marketing name. CompuServe has just announced that at the end of this year, or in early 1996, they will have a separate Internet access service based at \$4.95 per month for three hours and \$1.95 [for each] additional hour.

There are a couple of different approaches here in strategy. GNN and NETCOM are pricing to give subscribers enough time to get an experience, to get a sense of the Net, to do some exploration. GNN has a slightly lower hurdle to get on, a little bit fewer hours, and Sprite is just for dropping that bar a lot lower in terms of the threshold for getting on before you kick into additional hours. So these are just different strategies.

I think you're going to see a lot of market testing and price testing over the next six months before some of this stabilizes for access providers on a national level; and there is a lot of competition at the local and regional level [also], and that will continue. At a national level, what that means is that you can call across the country [as if you're] making a local call, and it's usually a high speed call, a 14.4 or 28.8 call. And if you're moving around the country you can use your GNN account to log in anywhere. GNN is coming out of the box with about 600 "points of presence" across the country. I believe NETCOM has 400 points of presence, which are areas where you can call local phone numbers [to access the service]. They tend to be clustered around large metropolitan areas.

[Let's talk about] advertising and media sponsorships. In advertising, six to eight months ago the top ten advertisers on the Internet were computer companies. What we've seen in the shift during the last six months has been the emergence of a pretty strong consumer brand presence, a consumer product presence on the Internet, as well as a pretty strong business presence on the Internet. So we've moved from Sun and Hewlett-Packard and IBM as advertisers to MCI, MasterCard, and Visa is coming, and America Airlines and a few others. There's a lot.

And there's a site called "WebTrack." They've published an advertising newsletter, and they also have a Web site and a list of the major consumer advertisers. Their URL is www.webtrack.com. Somewhere in that site it will give you a pretty extensive list; I think there's over 300 consumer and professional advertisers with links to that particular site. It's actually a very nice feature. [It has] drug companies, pharmaceutical companies [with a] heavy Internet presence, and advertising in certain scientific areas as well. But the trend is toward sponsorships, and this is pretty interesting for me and for the industry.

The advertising that started on the Net about a year ago was traffic-based, which is [a record of] how many "hits" were coming. That was basically — either that was what the price was based on or that was the rationale for charging a certain amount of money. Now we're seeing a shift as new programming and original content moves to the Internet, and the pricing is shifting away from traffic-based to content-based. Actually, there is both.

Here we can see a move from directory style traffic to sponsorships that are lifestyle-based, and this fits the consumer model. This is where we begin to move in sort of a blending of magazine publishing and cable TV programming; and that [new blend of] programming is used a lot in the consumer end of the on-line and Internet industries because we are creating new content for this particular medium.

AOL has a greenhouse program, and the other on-line services have developer programs where we're actually helping people, giving people the tools to provide and create new content. I'll get into some of that a little bit.

In terms of lifestyle, here's one example in the GNN service. Of course, the default screen is the GNN Web site, which has been enhanced over the last few months to bring in articles written by Paul Thoreau and Jan Morris, who are travel writers. We have interviews with Robert Mondavi, and we've serialized books, some new books, some recently out, some soon to be out. And [we've also] created some other [areas that] we think are pretty interesting and interactive areas; but in terms of lifestyle, we've actually developed some new articles and features that deal with travel, personal finance and sports.

The "Story Cafe" [category in GNN] is for books and literature, both of an interactive nature and of a page-based nature, where we have bulletin boards and chats going on with famous authors about their book or about chapters of their book, and we'll run a chapter [of that book] a month over a series of four to six months.

In "Education," we do some partnering there with other educational publishers and Web Review. Web Review is a magazine of social commentary that actually was created for the Web, and it's authors and writers are some of the early writers for GNN before O'Reilly sold us to America Online. They stayed to create this on-line magazine, and it actually has a pretty good technical edge to it as well as employing a lot of technology. It's one of the most active sites using real audio today.

Now, what are we looking at in terms of prices for some of this stuff? Well, on just the traffic-based sites, the WebCrawler, which is a search service — I guess when we look at some of the directory-based products we're looking at browsable indexes and searchable indexes.

The WebCrawler is a searchable index. It's a spider that crawls, identifies Web sites and indexes them, and then you do a search and it will tell you what it's found. The WebCrawler gets

about 11 million queries a week; that's based on last week's figure. A billboard ad there is \$22,000 a week.

The NCSA *What's New* page, which is jointly published by GNN and NCSA, has a price of \$11,000 a week. It gets fewer hits than 11 million; somewhere in the tens of thousands or hundreds of thousands. And the *Whole Internet Catalog* has been renamed the *Whole Internet Catalog Select*, and it's now positioned as it should be, which is as a selected listing of interesting, content-rich Web sites. That's on the Net, but it's within GNN, and that gets a billboard ad at about \$3,300 a week.

M: Do you correlate the cost of the demand for [inaudible] advertising [inaudible].

Patricia Sabosik: Well, 11 million people see it.

M: See that ad?

Patricia Sabosik: They see that ad, that's correct. So there is some correlation between price and exposure. This month, in September's issue of *InterAd*, which is both the on-line and paper-based newsletter from WebTrack, there is a pretty interesting article about the correlation between the CMP for on-line advertising versus paper advertising. There still is a much more efficient relationship between print ads and reader circulation, reader view, than there is for on-line; it just depends on how we're counting. This is still new.

Here are some others. ZDNet costs about \$40 for three months, and they figure their page requests are about \$1,500 per week.

This is on TechWeb, on sites that can either stay in an area or rotate around TechWeb, and that's a pretty interesting site. If you haven't seen it, go there; they do some very nice things with both their magazines and newsletters, all advertising-based, supported advertising.

M: [inaudible]

Patricia Sabosik: Oh, that means how many people are expected to access the Web page, where that ad appears, per week. The CMP can be somewhat specialized, so they've got a niche audience. They've been doing this for a while and they have a pretty stable readership base in different areas. *Wired* pages [cost] \$15,000 per month, with requests at about \$1,300 a week for that particular ad. *Wired* counts its readership at about 750-760,000 readers; [that information is from] *InterAd* in September.

[On the subjects of] memberships and subscriptions, these are merging and actually moving into the quite developed areas on the Net. They're ways to identify readers, to capture information on usage and to capture demographic information. I'm going to talk a little about that towards the end.

An important way to know who is in your site, how they are using the information, where they are going — a lot of that can be tracked as the browser technology gets more complex and sophisticated and server technology gets more sophisticated. These things can be tracked in a much more rigorous way than they could six to eight months ago. And here are some examples of sites that actually do have membership forms or demographic forms that say, "Hey, tell us a little bit about who you are."

At GNN we've had one since the site began, and that was in 1993. We're an old-timer in marketing and pushing on the Internet. CMP is another site that asks and actually gets a very decent response rate, even though this is all voluntary. These are voluntary ads. WebTrack will ask you for information if you want to access some of its lists, which are for free, but they want

to know who you are before you get into that particular list. It's clever; it's not very obtrusive, but it's there. America Online has a voluntary form to fill out on their Web site. *Hot Wired* does as well. I think you need to do that before you actually get on to *Hot Wired*.

ESPN, also has membership information, and that's actually a subscribed service where most of the sports information is available for free. There is some premium content that is available now for a fee, and I think the fee can run up to \$30 or \$40 a year for the threshold plus additional dollars per hour. You will see more of this as restricted access becomes possible where it didn't before, and as security — whether it's the Netscape-based SSL, [which stands for] "Secure Socket Layer," or secure HTTP — becomes much more pervasive, you will begin to see more of these types of services developing because information providers would like to get a little money from this medium. As more commercialization moves forward to the Net, we will begin to see more of this.

"Transaction services" is another revenue area or cost area. This is very much an emerging business, with Internet banking and electronic cash, where the bank takes a percentage of the transaction fee as a handling fee or an overhead fee. The security that's in place today, as I mentioned, is new. Most of it came out of the [Teresa] joint venture between the major on-line services and Netscape, where both agreed to adopt the same standards for security; and they're there. They're in most of the commercial browsers and also beginning to be implemented into both the commercial on-line and Internet services. And all that does is lay the groundwork to be able to then say, "Yes, we can have a secure transaction. Yes, I can take your credit card over the Internet or I can send a confidential message. I can send something that's secure over a public medium."

DigiCash just announced their service working with a bank in St. Louis to set up commercial transactions using their file. You basically set up an account with an up-front deposit, and the things are debited from there.

M: [inaudible]

Patricia Sabosik: Oh, small: one percent, two percent. That will probably be all over the board. They're lower than the current credit card services, but I think we're going to see a lot of variation before that settles down. The toolkits to develop this technology were just released over the summer, so really we're just in the infancy stage on this right now.

Here are some products that we can begin to see that can be revenue-based, and can definitely be service-based. I guess we can look at revenue. [These products are] either providing revenue directly, or it's keeping someone connected, and that's providing a revenue stream. And they are original programming, news services, personal Home Pages, and community-based services — and this means an interactive, on-line community, not necessarily for your neighborhood, but then the definition of neighborhood is changing as well — and hosting services. I just wanted to run through a few of these.

When we talked about original programming, the GNN Voices have content that was written specifically for this program; and if we consider this an on-line magazine, then these stories and interviews and interactive areas are specifically designed to reach a certain readership. *Hot Wired* is designed to reach a certain readership; there's a hipness to it, an edge to it. There's an attraction for a certain demographic group.

Sports Network, which was just launched about a month ago, is a joint venture between the Sports Network and WAIS, Wide Area Information Servers. It has real-time news feeds and sports scores running all day long, plus news stories, plus pretty deep stats in a bunch of different areas that don't exist in any other medium. It was pulled together to be a specifically on-line broadcast tool, and it's pretty neat. And *Web Review*, which I mentioned before, has

social commentary, technical commentary, and education. They focus a lot on the higher-ed market and college students, and what's going on there.

What are the technical issues and social issues involved with that, and with those writers who are writing and dealing completely in an Internet-based environment?

Before I go into the news services in AOL's greenhouse, [I want to mention that] Microsoft has a developer program, and CompuServe has a developer program, and they're also designed to help creators, authors and developers create new material for this new medium.

Now, about news services; they are very much a growth area on the Internet, and pretty exciting as well. I think more than 50% of the country's newspapers today have a Web site with news content on it. News Pages is one pretty good example, published by Individual, Inc. It's a subscription-based service where you can search in different areas and get current information. It focuses on the hi-tech computer interactive industry, so it's not general news, but it's there.

The Crayon Experiment... I don't know if any of you have heard of Crayon, [which stands for] "Create Your Own Newspaper." It's being run now as a research project, out of Bucknell. It's got 10 or 12 categories, and within each one of those categories is another ten examples. You profile the order [in which] you would like to get your information and the sources [from which] you would like to get your information; they'll store your query, and you just do a reload every day and you get your news packaged that way. It's pretty neat. You miss stuff you don't want to see — like sports, you know, I may never see — but it's an experiment.

As I mentioned, newspapers... More than 50% of them are on [the Internet]. *San Jose Mercury News* does a good job of getting news from the Silicon Valley area on the Net. *InterAd* monthly. CMP does a nice job of publishing their newsletters and some of their magazine information. Ziff Davis as well. *The Washington Post* with digital ink, that's going through Interchange. So we can see a lot of information-based services moving through on the Net. It's a nice medium, doesn't require a lot of graphics. Reuters New Media [is] also very active in pushing its content onto the Internet. These are two people who have licenses to Reuters who are bringing news feeds directly into a Web site: GNN and *Yahoo*. There might be more; I think Reuters has about ten Internet-based services licensing their content, possibly more. AOL and the major on-line services have it as well. It costs money, but you'll begin to see that pop up on other Internet sites as well.

[Now let's talk about] personal Home Pages, the fun part of the Internet. It's a developing communication form, and I say somewhat jokingly that it's a communication form, but in a way it is because it definitely is a form of personal expression for people who are exploring a new medium. There's an emphasis on interactivity and definitely on personalization. And this is an area that is another characteristic of the Internet as it moves into more of a commercial service. If you're thinking of developing programs or publications for that, personalization is important. Also, if one of the ways of measuring your revenue is connect time — which is one of the underlying measurements or principles behind both the on-line services and the national Internet-based services — we make our money the longer people stay on-line, [rather] than just having something that they can go back to time and time again. This becomes an important service as we grow our communities.

GNN has had an area for personal Home Pages and for personal links for over a year called "Nedisons," and that area will be enhanced with the ability to create personal Home Pages using NaviPress, which is another AOL technology. NaviPress allows you to author directly to a server without knowing HTML; you just sort of click and go there. Click and save and there it is. NaviPress and NaviServer also have their own hosting service, primarily for small to medium-sized businesses, but that's a feature where other services will have this as well.

The community aspect of it is important. [What is] definitely important in terms of Internet marketing and the big issues is identity. It gives people an identity. "Yes, I want to be part of this particular community and that particular community. I want to be part of the *Hot Wired* group because I'm hip. I want to be part of the GNN group because I'm a thinker. I might want to be part of the *Web Review* community," and so on.

Security. Can your community-based communications be secure? Can you send secret messages to people? Can you send secure messages to people, beyond just financial transactions? What about personal communications?

Granularity. How specific can you get? Let's say that in my neighborhood I want to talk to women in their forties who have one child and who went to graduate school. Well, that gets pretty narrow in my particular area, but I might want to find just that particular group, and you can go that [way] in this medium. You can do that very easily in this medium.

And then there's the interactivity, and that's becoming more and more important as people are reaching out in this medium. Some of the examples are "Chat" and "Bulletin Boards." I think we're going to see more personal services that are less on the seamy side and more on the sort of interesting side. Match.com is a good example; they guarantee anonymity. They've got a whole series of checks and balances and security in place to do that, and they've been pretty successful so far.

[Now let's talk about] audience and survey time. I'm going to run through about six surveys that are either in the process of being conducted or have been conducted. And let me just say, before we get into some of the specifics — because I'm not going to get into the specifics of each survey — but what's interesting from a marketing perspective is that we're now at a point where taking these kinds of surveys will provide some meaningful information. There is enough of a critical mass of users on the Internet, either business related or consumer related, that can give you a valid sample of what they're doing. At this particular point the pulse is being taken by a lot of organizations, and that's pretty interesting.

Yahoo had 63,000 respondents to their Web site on-line survey, and Jupiter Communications is publishing that. O'Reilly and Associates is in the process of a multi-phase Internet-user study. Highlights [of that survey] are that 66% [of respondents] are male, ages 18 to 44. The Times-Mirror Center for People in the Press conducted an on-line survey, and those results were published last month. [That survey showed that] 53% use e-mail at least one time, once a week and that 30% use on-line and Internet services for news. That correlates directly to what we said before, which is that news is an emerging area. Intecho Market Research Company has published a survey on the number of households that have modems and are using on-line services. [A survey from] Simba Information [showed that] 80% of users are willing to accept the Web as a commercial medium. Now that's pretty good; that's a pretty good test and it gives you an idea of where we're going.

When the National Science Foundation began to pull back its subsidy, there was, I guess, a culture clash because most of the users were academics and didn't want commercialization to run through [the Internet]. So we've definitely seen a mind shift there...

Women are a growth area in terms of using the Internet and on-line services.

DataQuest is in the process of summing up its study, but they found that 60% feel that security is very important and this will lead to more information on consumer transactions.

CNet deals with computer and technical issues and so it's no surprise that 92% of their users [in their survey] are male. 62% [of the respondents] completed college. Throughout all of these surveys, what we see is highly educated people earning in the average range of \$45,000 to \$80,000 a year; so we're definitely in the high-income end of the market, and that would also map directly to the fact that we're shifting from that innovator to the early adopter market. The innovators are not price-sensitive, so we're seeing the swing into more of the mainstream.

Chiat Day has coined the term, “screenagers,” which is sort of cute.

In marketing it's important to have an outline, as you're looking at both designing a product and trying to sell it through this new channel. Is the content “Webcentric?” Is it Web-oriented? Is the context of the content interactive, and how are you placing and positioning your content on the Net? Does it have a nice design flow? Does it have some original material to it? What community are you reaching now that we're beginning to get some demographics on all this? Who is the community? How are you designing your package to reach them? What's the commerce component? Is this for free? Is it being subsidized by advertising or subscriptions or both or is it just being sponsored completely by another organization? What's the connectivity? Connectivity can mean the other people or groups you are connecting to, or [it can mean] how you are getting there. Is it on your server? Is it on someone else's server? Are you hosting it? Is it part of a larger group? What's the cost to get on, and the cost to handle this?

Here are a couple of other summations on the marketing end. [Regarding] distribution in the early adoption stage, use OEM strategies to expand the installed base of technology so that you can actually have something there to use. How many people have gotten a diskette from Prodigy or AOL or CompuServe? AOL “carpet bombs,” you know; that's one way of doing it. This fall, this holiday retail season, every computer that you buy will have at least one on-line service burned into the disc, burned into the hard drive. You have the option of deleting it, but they'll all be there. The on-line and Internet service companies are looking at ways to create an install base so then you can say, “Okay, now I'm going to use that.”

And they're doing it through technology, with PC bundling, modem bundling... You buy a modem; it either comes with a free offer or something is burned in. Custom browsers link to a Web site. The NETCOM default site is the NETCOM Home Page. Volkswagen is using, I think, *Mosaic*; they've bought a certain number of browsers. It's on a diskette, and you get a certain amount of service, but the default Web site is the Volkswagen site so you get to see their new cars. It's a limited promotion just to see how that plays. Compaq does that with other browsers, and you'll begin to see more of that as well.

And so what are the business models that are really emerging in this new medium? Magazine publishing, specialization by subject, by lifestyle, by niche, TV and cable programming and distribution — because you're working in some ways with broadcasts and in others with “narrowcasts” where you can broadcast to a very wide audience, millions of users if they choose to come. Just like TV or narrowcast, [you reach out] specifically to a group who knows that every Monday at 10:00 people like them will come and chat or people like them will come and use this.

We have a little bit of that as well, and [we also have a type of] syndication where sites can be licensed in certain different areas or certain different other Web sites and other services. The early days of syndication are developing right now, but that will grow over time as well. This is my ending screen: gnn.com. Mission arrived... You won't be disappointed.

Thank you very much. We have time for some questions.

M: [inaudible]

Patricia Sabosik: You have a property that runs in different Web sites but you don't change anything, like Reuters syndicating their news. “Dilbert” is syndicated, both in paper and electronics. *The Web Review* — that magazine is going into syndication, so it will possibly be hosted; we're looking at that hosted on different Web sites. GNN is hosting their own version of *Yahoo*, so *Yahoo* is looking at syndicating it's indexing. They're soon to be on CompuServe as well.

M: [inaudible]

Patricia Sabosik: With the hosting services today, the pricing model for that is based on size with a component of usage. Usually it's 5 megabytes, 10 megabytes, or a 100 megabytes, so it's mostly storage; and then, assuming that that size of a file will reach an average of 2,000 hits a week or 3,000, there's usually a premium charge beyond the threshold of so many hits.

M: [inaudible]

Patricia Sabosik: Oh, actually I see that coming very soon. One of the small business growth areas is something that we call SOHO, Small Office and Home Office businesses. There are going to be services designed specifically for them, I would say within three months.

M: [inaudible]

Patricia Sabosik: I don't, but you can get them from those specific Web sites, and you can find a list of those Web sites in the September issue. You may have to subscribe to get it but most of those companies will post something about their surveys on their Web site. O'Reilly is already, TechWeb, CMP is posting, Yahoo posts, and Hot Wired will post them as well. Chiat Day won't; you have to buy that.

M: [inaudible]

Patricia Sabosik: Oh, you probably could find it on that site, and there's a few companies here that are providing hosting services. You should go there and just ask them. NaviPress is one. It's called NaviServer, and they're out in California. There's a few other services that actually will do hosting for you.

Gutenberg

M: [inaudible]

Patricia Sabosik: Oh, a new Intel chip. Well, the smaller information access providers might disappear. To be candid, the consumer side of the Internet is reaching a mass market. It's a numbers game, and so larger [companies] will be able to amortize a lot of fixed costs over a lot of people, which means at some point — right now they can't compete with the smaller access providers, but within a few months, six months to a year, I think they can. In that case they may put the smaller access providers out of business. WebCom is the company in California that does a lot of hosting, and they do a nice job with small businesses and personal Home Pages.

M: [inaudible]

Patricia Sabosik: It's possible, but I think you're going to see more customer service aspects built into national providers just to try and compete at that level. You may still have the competitive advantage on price, I'm just not sure how long you can hold that.

M: [inaudible]

Patricia Sabosik: I don't think it would be profitable in the long haul because the technical support to maintain that isn't the core business of an agency; but getting something up and

going for three to six months is a very natural thing to do and there is some profit in that. I think an agency would need to build to a hands-off point at some point in time. The critical mass of Web sites that you get up puts you into that server forum environment. You've got security issues 7 times 24, and maintenance issues, and it gets really expensive really fast.

M: What kind of ratio [inaudible]

Patricia Sabosik: Modems to subscribers? With GNN it's one. With NETCOM I think it's one as well. With AOL there's an overhead, and I think the other on-line services...

M: [inaudible]

Patricia Sabosik: Yeah, it can range anywhere from \$1,200 to \$12,000, depending on how complex you want it, what you're hosting it on, what kind of a design element is in it, and who does the HTML and how big it is. Is it 100 pages or is it 200 pages? I worked with a small group of academics to put up a Web site of about 50 pages that's going up soon, and we did the HTML and it cost us about \$600. Somebody else is hosting. So, that's sort of the [cost] range.

It depends on what you're trying to do. Once you add a lot of graphics, image maps, and CGI to get interactivity and to collect that, that server where you're hosting it has to be configured for your CGI scripts. It has to be configured for the image maps, so putting it on your local file is one thing, and getting it to the server and getting the server to recognize it and then having people be able to click in... It just adds different layers to it.

And in this medium, the salaries right now — as we're shifting — still have that technical edge to them so they tend to be a little higher than they would in the traditional publishing industry or graphic arts industry. That will change, because as the market pushes the price down it will push those salaries down as well. Does that answer your question, sort of?

The question is, if people are very skilled at Web site design, what's their salary? I said between fifty and eighty [thousand dollars]. Price per hour? It can range from about \$50 an hour, to \$75 an hour or higher. It's pretty high. A lot of agencies are moving into that business as well.

Thanks a lot.

INTERNET PUBLISHING PRICING AND PRACTICE: A PANEL RESPONSE

MODERATOR

Patricia Sabosik

Editor-in-Chief, *Whole Internet Catalog*, GNN, America Online Inc.

SPEAKERS

Tristan Louis

Publisher, MecklerWeb's iWORLD

Matthew Shevach

Market Development Manager, MecklerWeb's iWORLD

Matthew Shevach: I'm Matthew Shevach and I'm from iWORLD, Mecklermedia's Web site, and I'm responsible for our market development. I'll be here to answer your questions regarding anything from advertising sponsorships and developing marketing plans to general pricing questions on developing Web sites and costs and revenue [inaudible] related to developing Web sites. Tristan here is also from our iWORLD. We're missing one panel member, Joel Maloff. He should be here soon. Let me pass this over to Tristan for a second.

Tristan Louis: Hi, I'm Tristan, publisher of iWORLD, which is Mecklermedia's Web site. Obviously, we've got all the bases loaded between Matt and I. We're going to try to answer all your questions on essentially how much it costs to run a Web site. We'll be happy to entertain any of your questions.

Patricia Sabosik: Let me start by asking you a question. One of the things that came up in the last meeting.... [By the way], I'm Pat Sabosik, Editor-in-Chief of the *Whole Internet Catalog* from GNN, AOL's new Internet service, and I recognize some of the faces here. I just spoke before on pricing.

In the last session there were, at the end, some questions on what it costs to develop a Web site. Do you have any numbers, or a sense of what sort of formulas you could put on the ratio of complexity to the number of pages?

Tristan Louis: Well, it all depends on the extent to which you want to develop your Web site. Developing a Web site can cost anywhere from about \$10,000 to several hundreds of thousands of dollars, depending on how extensive you want it to be. We just went through a complete redesign with ours and went easily into the six figures.

Matthew Shevach: I think one component that's going to raise the cost of your Web site a lot, and I think Pat touched on this in the session before, is in terms of the complexity. If you want to do something neat that's going to require access to your CGI BIN or things like that, if it's not just an out-of-the-box solution, [inaudible] require some servicing, some man-hours from your access provider or your service provider, that's going to raise your costs significantly. There are a lot of service providers that will give you an out-of-the-box solution. If it'll just be giving you space, access or directory, or just going flat content, it will probably be pretty cheap. They're going to price you based on how much size, maybe based on how much access. But if you're really looking to do something that's interactive in the sense of producing pages on the fly or producing queries from a database, it's going to cost you some more money and you're going to have a little bit more development. It would also pay to try and bring some of that stuff in-house because you're most likely going to be paying hourly rates to a developer to do that.

M: [inaudible]

Tristan Louis: Okay. The question is, do we recommend UNIX or NT? It all depends, once again, on what you want to do. Historically, the Internet has been a UNIX-based platform, and as a result most of the tools right now are running on UNIX systems and are being developed for UNIX systems. However, not all UNIX systems are alike. Sun has very much of a lock on this industry, so usually if you want to go with UNIX-based, you might want to consider them as taking the lead.

Windows NT is a product that is gaining some ground. Microsoft has been pushing it hard and is planning on pushing it even further with *Blackbird* which is the new authoring platform for the Microsoft Network and eventually for the WorldWide Web. And we could see NT become a very strong contender in the very near future.

M: [inaudible]

Tristan Louis: Well, at iWORLD we've taken a very different approach. We haven't gotten into a platform-specific architecture. We actually run NT servers, Solaris, AIX, different flavors. It all depends on what you want to do, how strong your database is. There are a lot of database engines such as Oracle and Sybase that work very well with the Web, and those companies have been pushing really hard for those to be fully compatible with the Web approach.

Microsoft is currently working on developing a set of tools that will allow you to access their sequel and its access database. We're still not at the point where we're doing database access, which is why you guys haven't been able to do registrations on-line, but we are seriously considering it.

M: [inaudible]

Tristan Louis: We haven't made a decision yet.

Matthew Shevach: We're using a flat-file UNIX database for most of our applications right now. One interesting development is Oracle; I think they're going to do a press release this afternoon. We'll be shipping an Oracle browser, I think it's called *Power Browser*, that will include an SQL library with their browser.

This really identifies a trend in terms of Web publishing from the flat pages, just HTML, to a more dynamic type of page. The FedEx site would be a great example of this, of pages that are created that have never been created before. You're going to enter your tracking number, your destination country or city, and you'll know how the page created the track on your package. This is coming from their existing corporate database. They're not designing a new database, dumping data in there and tying that to their Web site; they're actually typing a front end to their corporation through the Web, and that's where Oracle's trying to go, I believe, as well with their announcement they're making this week.

Patricia Sabosik: I have an answer to some of that. The GNN Web site is also UNIX-based, but we have a number of our properties sitting on WAIS, indexed by WAIS, and we're using WAIS as a query front end and also as a way to manage some of the data, particularly in our directory areas. Verity is another. Oracle and Sybase are big, industrial strength packages, so if you don't have a lot of content, it won't work. Verity will bring you down to scale.

M: [inaudible]

Patricia Sabosik: The question is, on platforms, how does OS/2 compare with UNIX and NT?

Matthew Shevach: I think that largely we were talking about server software for platforms, and OS/2 really doesn't exist in terms of the server platform, as far as I know. I don't know anybody who's using an OS/2 server. IBM's UNIX AIX, they have a server platform for that and we've actually been using that for some time. OS/2, on the client's side — they do have browsers, I think, Netscape has reported to OS/2. IBM has their own Internet explorer and you can, of course, run your Windows applications through OS/2, so that's not so much of a concern. Does that answer your question?

M: [inaudible]

Tristan Louis: Well, *WarpConnect* was a platform for OS/2 to be able to serve the Internet. They never really expanded it to a full offering and page-serving set. With last July's announcement by Lou Gerstner that OS/2 wouldn't be supported on the PC platform — I don't want to speak for IBM, but it looks very doubtful that IBM will support OS/2 as a publishing platform.

Patricia Sabosik: That's right. I think they admitted that they lost the desktop battle and it's primarily Windows and some Mac users.

M: [inaudible]

Patricia Sabosik: Well, I think in terms of the on-line services that Macintosh represents — depending on the service — anywhere from 20-30% of their users on that, and it's not dead yet. I think that with their plans to license their technology they're moving into at least holding their position, and I see them holding on for quite a while. Not on the server end, but definitely on the client end and as a desktop solution.

Tristan Louis: Well, I beg to differ. On the Internet, I think Macintosh has some huge potentials. They've been rolling out PowerPCs like crazy, with HTTP servers and a set of [inaudible] and CGI BIN programs that allow for anyone to use a Macintosh as a Web server.

Patricia Sabosik: So this would play into their new strategy to change everything to be "Internet-centric."

Matthew Shevach: I think the Mac, generically, is a lot easier to use. On the server side you can do some easier things, I think, with the Mac in terms of scripting for your CGI using *AppleScript*. It's certainly a lot easier to use, and there's some nice servers for the Mac. The WebStar server, some servers out of StarNinetechnologies. So I wouldn't write it off yet.

Patricia Sabosik: Have you looked into 4D as a database? I built a database on a Mac platform, an Internet directory of about 20,000 sites with multiple descriptions and three or four levels of headings using 4D, and we ported to UNIX, wrote an HTML script converter and published to the Web pretty seamlessly and very nicely. And it was an easy system for four or five editors to manage the content and to update very easily, or by its re-service bureau.

Tristan Louis: Yeah. UNIX requires a lot more support than a Macintosh would, unfortunately. UNIX was originally designed as an open system to make it possible for anyone to get into the system. Unfortunately, that means that it's also been open to hackers, and if you don't have a full-time staff really writing your UNIX system you'll find yourself getting into some trouble at one point or another.

M: [inaudible]

Matthew Shevach: Oh, it's a tough question. I once got asked that same question by someone. The question was, are you a service provider? From a service provider point of view, in terms of providing access to the CGI BIN — the cost of the security risk, or maybe the risk of people using a processing time by giving them access to your CGI BIN versus having them write their CGI and then having to re-code the CGI for them — how would you balance that? I certainly think there is a risk in terms of allowing people to write their own CGI. They could be writing CGI scripts that just loop over and over and not know it — and you'll find out, I'm sure. I would stay away from it.

I think a nice middle ground may be to set forth some guidelines and maybe work with an integrator, or if you have someone on your own staff, to actually design some standard scripts. There's a lot of scripts out there on the Net right now and I'm often referring people to script libraries. If you can pull some of those together on your site for people to use, that could be a nice middle ground where they can put those together and then have access to loading those scripts and configuring those scripts. But for just free-form CGI, you may want to stay away from that.

M: [inaudible]

Patricia Sabosik: Well, the first is, what would we need to keep that? One is a larger base of PCs and modems that can handle higher speeds.

For example, the GNN Web site requires you to have Windows and a 486 or higher to get a good experience out of this, and also a modem of 14.4 or higher. And I think that with most Internet sites, as they become more complex, you're balancing an experience versus access. So to have a good experience you need that or higher, and 60% of the PCs in homes today are not that; so about 40% of the home users can have a good experience, but 60% can't. That needs to change, and I think the OEM bundling of both the access modems and CD-ROM drives installed in PCs will help to extend that technology base. But that absolutely needs to be in place before you can get a larger market share.

And also the technology needs to be easier to use than it has been up until now. Even today, if you have more than one on-line service, you have competing TCP/IP connections. You've got competing DLLs and one is going to knock out the other, because your system is just set up to use one — unless you can figure it to accept more than one, and that's not that easy to do. I have a few on my laptop and I know I always have to reset everything if I bring in another service. And I'm technically [proficient], but a lot of people are not, and it was not easy to learn. But anyway, you do what you have to do.

The average consumer, in order to make this a consumer market, doesn't want to know this stuff. That's why Apple is so great, because you don't need to know. You just plug it in and then things happen like magic, whereas in Windows — with Windows 95 things are getting easier, but they're not that easy yet. In a UNIX environment — well, a UNIX environment is not for the consumer market. So those are some of the things that absolutely need to happen.

In terms of testing and pricing, that will go on and it will go on at a grander scale than it's going on now until we can get some market shake-out. As to what will be a realistic price, the connectivity for Internet access is probably driving towards a dollar an hour. It's not there yet, but it's about to be. It was about three dollars six to seven months ago on average, so we dropped almost a dollar in a little less than a year. You may have another year to go before that shakes down, until [you have] market acceptance of this technology at a price that the market feels comfortable with — and two or three dollars an hour an average consumer doesn't feel comfortable with. So, those are some of the things.

Tristan Louis: In my view there is not going to be any stability in this market, at least not in the foreseeable future. As you may all know, the Internet requires a certain level of education, and as it was pointed out, unless you've got [sufficient enough] capabilities to get on the Internet you're not going to enjoy that experience. Furthermore, what is missing is a real standard on the Internet. We have standards committees, but more and more you have companies like Netscape and Microsoft coming out with proprietary extensions which are only supported by their own browsers. That has created a certain amount of instability in the market and it looks like things are going to get worse as times goes on.

Matthew Shevach: Just to add on, in my point of view I agree with Tristan in the sense that we most likely will not have one party controlling the Net. Even Netscape themselves, in their awe-inspiring massiveness today, probably will not be able to control and set standards, because we've seen that users are not as loyal to their products because it's very easy to get another product and it's very easy to distribute a new product.

Another thing I think a lot of people ignore when looking at Internet users is the lowest common denominator of Internet use, which is e-mail. The number of e-mail users and the standards for e-mail are a lot more established, and I think you're going to see — actually, I know you're going to see — some really interesting stuff in the next few months, stuff like free accounts and free e-mail access to the Internet. There's two companies, one called Freemark and one called Juno, that will be offering advertiser-supported products that will let you get free access to the Internet and e-mail accounts. Whether or not this will yield further on down the line to full Web access is yet to be seen, but that will add some stability on the lower end. E-mail is a productivity enhancer and a communication tool, and will probably become something that's much more intrinsic very, very quickly.

M: [inaudible]

Matthew Shevach: Freemark Communications, and I think they're... Juno's in Manhattan, an offspring of an investment operation. Freemark is partially owned by a company called CMG Information Systems. Freemark, I know, is very close to beta testing, and have been participating in that. They're a few weeks out, I believe. I'm not quite sure where Juno stands, but certainly by early '96 we'll see those rolling out. The model, once again, is advertising within the support of the actual application to give you free access.

Patricia Sabosik: Yes. That Freemark feature will also tailor the advertising to the kind of information you want. So if you're a skier, they'll sell Rossignol and other ads that will match you, so that whatever you query on you'll get the ads that you're interested in. They're trying to match personal profiles with information.

Matthew Shevach: Well, I think at the low end of the market it's going to bring some people in that may not have come into this market yet. In terms of their acceptance towards advertising, I think it will be taken pretty well because I think the market we're talking about are the people that would tend to watch TV more in terms of the displacement factor. Because if you look at it, people who use the Internet a lot tend to not watch a lot of TV. The people who are out there, who don't use the Net and maybe don't have the technological know-how or the incentive to go out and do something that may require a little effort, would be the market that this would attract. And it will be very easy to set up; it will be a one-shot deal in terms of the access and the application because it won't be all the bundles and features added in FTP, Telnet, Web — it'll just be e-mail. So it may be stability on the low end, but I do think it will add some confusion to the mix and it's going to obviously mix up the pricing model for a lot of other people.

M: [inaudible]

Tristan Louis: The question is, regarding the instability of HTML standardization, what do content providers do to deal with it? It's a difficult question. There is no doubt you could go in and use all those proprietary extensions, and yes, they would make your life a heck of a lot easier. Netscape has been pushing their extensions a whole lot, and what we have done at iWORLD is that we've decided to only include Netscape extensions that are supported by at least two or more browsers.

Now, the browsers we've chosen we're also not taking out of the woods. One of them is in *CSA Mosaic*, which is always supporting the standard HTML. They're sticking to the basics. The other one is the American Online browser — not the GNN browser, [which is a] very different thing. And the reason we've taken the America Online browser is that it seems to be the lowest common denominator, and this is one to deal with.

Patricia Sabosik: That's our browser group. Booklink Technologies was bought by AOL to give the AOL users a Web browser. So we built that into the client [server], but the browser was fairly powerful, so we stripped it down in order to work in the AOL environment, and it does give you a Web experience and it is integrated with the AOL client. So it's essentially a Web client imbedded in the X.25 AOL propriety client.

The GNN side of the fence is much more powerful: OLE compatible, drag-and-drops, split windowpanes, multi-tasking, multi-threaded, and we do the same thing in terms of incorporating Netscape extensions. There are very few that we incorporate; we do some, but not all of them.

Matthew Shevach: I think another answer to the question is this: not only will people have browsers that don't support Netscape extensions, but people will have older versions of browsers, even older versions of Netscape browsers. So one of the things you can do — there's some neat little get-arounds you can use to support Netscape extensions while still making it look pretty good for the other people. If you assume the majority of people are going to have the best browser, say, with a table, you could also include coding for people who didn't have tables, so that it comes out on the page not all wrapped around each other, and looks nice. That's one of the things we look at a lot.

M: [inaudible]

Tristan Louis: Okay. The question is, essentially, would this customization of pages mean a smaller load on all machines? It's a good idea, and I'm personally all for it. It's not an easy thing to implement, but it's an added service to all customers and all visitors. However, it can put a tremendous load on your machine. There are tools coming out right now — you're seeing them come out of the woodwork, bit by bit — that will allow you to simplify that process. I think as the Web grows and as more and more people get on-line we will see more and more sites pop up with customized Home Pages.

Patricia Sabosik: Can I just answer that? Another rule of thumb is that that kind of customization, with today's technology, can add half-again as much overhead to your server environment in order to meet that demand.

M: [inaudible]

Tristan Louis: The question is, what are some of those tools and how much do they cost? NeXT, the company formed by Steve Jobs, has come out with *Web Objects*, which allows you to do customized Home Pages doing queries on databases and so on. I'm not sure of the pricing on it, but I know it runs into several thousands of dollars. It's not a cheap option right now; I won't fool you, it's definitely on the expensive side.

As more and more companies are going to come out with such tools, I think we're going to see a market that is going to get a lot more competitive. As a result prices will go down, much like in all the other markets such as Web-authoring tools and so on. I'm not familiar with *Interworld*, so I can't say whether it's in that category. *Web Objects* is not shipping just yet; right now there are a few privileged ones who have had a chance of seeing it, [but I have] no idea when it is shipping. They've been moving that deadline around all the time.

Matthew Shevach: Today I was out and saw Steve Jobs speak on the release for *Web Objects*, and from what I recall they're in alpha right now, they'll be in beta the last quarter of this year, and they'll be shipping in early '96. But as Tristan said, there are some sites that have been using the NeXT tools as a development partner. I think the Dodge site and I think FedEx might have used some of it as well.

Patricia Sabosik: The *WebCrawler* runs on an indexed platform as well. The market that we're headed for with the robust GNN browser is the personal Internet user. We're looking at someone who is technically advanced; we called them TAFYs, "Technically Advanced Families." It's consumer-oriented user in the home. So we're looking at business people who want Internet access at home rather than in the office and students who are graduating and want to keep that Internet fix. We're targeting the college market and the post-college market, and we're also targeting students in high schools and grammar schools that want Internet access and don't want to go through an on-line provider. So it's families, business people and students.

The SOHO market is one we're also looking at. SOHO, for those who weren't here before, is the "Small Office/Home Office" user, and we're absolutely looking at that market as an add-on. We have a small service now within GNN called Business Pages, which allows small users to advertise their products. We have standard forms where you can buy through us, and that will be beefed up. We also have some larger organizations that will be sponsoring some interactive areas just designed for small businesses as well.

M: [inaudible]

Tristan Louis: The question is, when you're adding all those tools such as chat, news threads or [inaudible] and so on, do we actually have a strategy? I could say no and make a lot of news, but I'm not going to. Yes, we do have a strategy.

It's become very clear by now that interactivity on the Web is essential. If you want users to come back to your site you have to make it interactive, and therefore you have to evaluate a bunch of products and be very careful as to what you're going to select. You want to make it as easy as possible for users to use. You also want to make it as cheap as possible for you to buy. There is a host of products that are available out there for free — yes, you don't have to pay for everything you put on your site. You can actually find a student somewhere out in the university who was probably bored one night and spent a lot of his time just coding a [inaudible] engine, and it happens to work.

For example, we re-launched our Web site and we're using HyperNews, which was developed by a couple of people at EIT. They give it away for free. We tested it out, we liked it, we made a couple of changes to it and now we're running it.

Then you have to look at other tools and think, well, maybe I have to buy this. It all depends on what level of interactivity you want to give your user, and I would recommend going with a high level of interactivity if you want your users to come back. And there's also how much you're willing to pay for it, and how easy you want those tools to be.

Patricia Sabosik: And time-to-market is important in this environment as well. So if you want all those features and you want them now, you may be buying them as post-components.

Matthew Shevach: I think, just to add a little bit on, that it's a double-edged sword, because if you are going to have time-to-market [as a consideration] you're going to be paying up front for something, but the chances are that down the road there's going to be something else. I think your strategy, although you need to have it, needs to be very flexible as to your long-term outlook — and in this business that [long-term outlook] is going to be very short, because there's going to be new products, new features.

And the other thing you're going to run up against is adding new tools on, tools that want to talk to each other but maybe don't. You're going to have some conflicts between tools, so you're going to have to be pretty careful in terms of evaluating things and there's going to be some pros and cons at each junction.

Tristan Louis: I actually want to add one thing. When we say "long-term outlook" on the Web, we are meaning probably nine months. I'd like to remind you that a year ago the big thing was *Mosaic*, that a year ago nobody had heard of such things as *Lycos* or *Yahoo*, or very few had heard of it. And now there's other big players on the market. So, in nine months, who knows who they will be.

M: [inaudible]

Tristan Louis: The question is regarding the maintenance issue of interactive content. Yes, it's a high cost of maintenance; I'm not going to fool you. We actually have a staff working full time and making sure that everything is running properly and everything is threading properly. And then you have programming issues, getting the right kinds of speakers in — it takes a lot of time. However, you'll find out that the time you put in is the time you'll get out. If you don't put any interactivity on your site, users are going to come in maybe twice and never come back. If you create a fairly interactive Web site, people are going to come back time and time again.

Don't forget: how do you pay for a Web site? Basically, right now, it seems to be advertising. How do you sell advertising? By selling to a number of people that came to your site. How do you get people to come to your site? By creating an interactive one. As far as management of interactive elements, no, there are no real tools. A lot of tools that are provided actually have the management suite built in. For example, in the case of the Net threads that we're running on our site for message boards, we actually have a [home] manager, front-end, that works on their X-Windows and allows us to manage our content that way.

Matthew Shevach: One more addition. I think one thing you really want to consider is possibly some good document management strategy or software in terms of looking at what pages are where, because when you get into a Web site that has 3,000, 4,000-plus pages it's going to start to get very confusing. Also, in terms of strategy and some guidelines: you're going to have a number of people working on this site, keeping copies on their hard drives at home, and you don't want to have people writing over things that other people are doing; so a document management strategy becomes very, very important.

M: [inaudible]

Patricia Sabosik: If it's Navisoft, as the division, then the authoring tool is NaviPress and your author to the server is NaviServer. It's not HTML-based, though there is an HTML converter inside the software. It's designed for users who are not sophisticated enough to be able to create their own Web pages, and to save them to a server where it creates HTML on the fly and is immediately up and available. So we're actually looking at a much less sophisticated market for that. We'll be using that particular feature in different parts of the GNN service. It's not in AOL yet, not because it's hard to use but because there are firewall and proxy issues, with writing to AOL servers. We've opened up one server within the GNN system to allow that type of interactivity. It still does sit behind a firewall.

That tool is designed for two markets: one is the Internet consumer market where they can create personal Home Pages, personal message boards and a certain amount of interactivity within certain sites; the second market is completely different and outside of the GNN service, and it's the small to medium-size businesses and the publishing business itself. It's a wonderful document management system in and of itself, and we do have some large corporate clients that have licensed that software to use internally as a document management and authoring tool. It can sit within your firewall and you can save it through an internal server. It's easy to change things on the fly and it also keeps track, as a lot of the authoring tools do, of links and the arrangement of links.

This one has the mini-Web feature. Interleaf's *Cyberleaf* has a tracking system that will check your links and also give you a map of what your site looks like. *WebSite*, which is software from O'Reilly, will also keep track of broken links. *AutoWeb*, a Mac-based platform, will do the same thing. So, that's sort of our strategy, those two particular market segments.

M: [inaudible]

Tristan Louis: The question is about how to price advertising for a Web site, and in this particular example it is medical publishing. I can only say one thing: low. Have very low expectations when it comes to advertising on the Web. Don't forget, there are over 100,000 sites on the Web and they're all going to want to pull in some advertising at one point or another. As a result, that makes a huge marketplace.

Prices right now on some of the most possible sites are just wild. They range from anywhere between a couple of thousand dollars to \$25,000 for one of the most expensive ones. If you go in and manage to get high enough traffic or deliver a specific audience to your advertisers, you can set up your advertising based on this.

But I would recommend that you start up low, get your advertising base in place and get all your positions filled, and once all your positions are filled let the marketplace dictate what your prices are going to be.

Patricia Sabosik: Medical publishing has traditionally had very high advertising rates in print. Why don't we take a look? Pfizer and Squibb and Merck have interactive sites on the Web today and they're doing internal advertising of their products. And if you're in that league, Merck is probably the most interactive of the large medical publishers. Also, the *New England Journal of Medicine* is advertising, so see what they're pricing. They have both the *Consumer Newsletter*, and bits of the *Journal* are in a Web site now and they're not that low. They're in the high thousands per week.

Tristan Louis: Once again, this is because those particular ones deliver a very specific audience. I mean, [let's say that] I'm Joe Surfer, and I'm not interested in medicine. I'm not going to go to the *New England Journal of Medicine* site or maybe I'll go there once, but I don't think I'll come back.

On the other hand there are more general sites. For example, take *Hot Wired*. *Hot Wired* appeals to a very general audience — it appeals to Net surfers. That's essentially how they define their audience. Yes, they're going to get a high head count, but say you're an advertiser that wants to sell tires. Would you rather advertise on a car site or on a site like *Hot Wired*? You're going to get a wider audience on *Hot Wired*, but it's not quite as specific. Therefore, you've got to look at what your advertising dollars are going to sell you. And when you're going to your advertisers, you're going to have to look at what kind of content you can give your advertisers.

In our case, on iWORLD we've actually decided to go after internal advertisers because we've decided to transform iWORLD into the primary source of InterAd information anywhere.

M: [inaudible]

Patricia Sabosik: These are two different things, the CPMs for print-based advertising compared with the CPM that you can get on an interactive Web site. Right now, there's a better cost/reader ratio in print than there is on the Web, but I think that will drop over time.

Matthew Shevach: I think also some of the larger sites, actually, InfoSeek and Lycos, their CPMs are actually much lower than the ones that were listed and their pricing is actually based on what they call an "impression." Of course, that's a very broad, general audience, so they would deem that a lower CPM. As you have a specialty audience, it may be higher.

The other thing that makes it very hard to compare is that you can actually measure things with the Web site that you couldn't measure in print. You can measure things on-line.

[You can say,] "Well, yes, they saw the ad in a magazine." One, you don't even know if they saw that page.

Two, on-line you can tell if they actually went a little deeper in and where they actually went. It sounds like in your case these advertisers don't have their own Web sites. That correct? Right. Yes, so we've been very lucky, obviously, in the sense that our advertisers are all

Internet product suppliers or Internet [inaudible] providers, so we don't have to worry about that.

So in terms of designing a product showcase for them, you may be able to sell them on the ability to provide information, sort of like a reader service card would in a magazine. And to them, I think there's a lot more value. So if you can price it cheaper and say there's more value, I think you may be able to sell them on that.

M: [inaudible]

Tristan Louis: The question is, how much experience do we have as to the accuracy of the data and the CPMs? That's a very interesting issue, because up until very recently there was no such thing as an audited Web site. When you get a magazine, you get an audited circulation. When you have the TV station, you get an audited number of people watching your show — the Nielsen Rating.

When you get a Web site, in a lot of cases you don't have any kind of audited data, so it's very easy to actually tell people, "Yeah, I'm getting a million hits." On the other hand, when you get an outside agency to confirm that, it may not be the case. Don't forget, a lot of people are selling advertising on hits. What is a hit? It's essentially one image or one page that has been loaded one time. Take a page that has 20 graphics on it; [if one person visits that site,] that's 20 hits. One person, one visit, twenty-one hits. It's very easy to drive your hit count up.

On the other hand, what you're seeing now is the big auditing firms from the outside world such as Nielsen, the BPA, the Auditing Bureau of Circulation, all teaming up with companies to audit Web sites. iWORLD is very proud to be one of the Web sites to test out a lot of those auditing systems. We've already announced that we were testing out the ABC and the BPA to audit our Web site, and we will be able to go to our advertisers and say, "Yes, look. We have an outside firm confirming that we have X number of hits." At that point I think that adds some value to our advertising, and I think that will confirm to advertisers that they want to go with us over another, unaudited Web site.

Patricia Sabosik: Are you doing any filtering with those hits or is it just an audit that the hits are legit?

Tristan Louis: Well, actually, what is happening in those cases is that the log files are not resident on our machine. We have log files resident on our machines, but we're also running a process that allows for the auditing firm to generate their own log file based on whoever comes in our site. So we never see the log files.

Patricia Sabosik: So are they filtering out by user?

Tristan Louis: Well, I can only speak for the Webtrack/ABC engine because that's the only one we've gotten up and running so far, but they are filtering by users and they can even tell us how long a user has spent on our site.

Matthew Shevach: There's some tricky questions concerning that. I mean, in terms of measuring users, a lot of people have looked at it and said, "Okay, if there's this many hits, there's this many graphics, let's divide by this number, and that's how many users you're going to get." That's very tricky.

One of the most common technologies people are using now is something called "Link Rewriting." You'll notice at a lot of the Web sites you're going to start dealing to that you see

this really funky code or insertion in your URL. What that's doing is that when you come in to that site, it's assigning you a code and then tracking you with that code based on the IP address or the session or the origin of where you came from.

It's going to be very hard, though, and I think that we're going to be sometime out from some standards even though ABC, BPA, and Nielsen are all getting into this. I think it'll be a while until we can agree what actually matters and then, when you tunnel down to it, to some things people aren't looking at yet. How many people came into your site, got this far and then just left through a link? That really doesn't mean anything. I don't really care if I'm an advertiser on a site and someone came in, didn't look at anything and just went to another site that they pointed to. So you're going to want to look at things such as rejection rates.

You're going to want to look at how many people spent a lot of time on one page, or actually went into an ad. You can tell if that's working at this point. But it's going to be awhile until advertisers have a way to just take a sheet like they do with a magazine and say, "Okay, this is it," compare it to this one and say, "Ooh, this one's better." That won't happen for some time.

M: [inaudible]

Patricia Sabosik: You might want to look at John Wiley. They were in some beta tests or considering some beta tests with the National Association of College Stores. Another organization is McGraw-Hill and their customized textbooks, and they were looking at an Internet delivery system. Right now it's paper-based, but they are doing some work, have some joint ventures with EduCom, and I know they were moving in that direction.

Also, check with the National Association of College Stores because they had a pilot project, at least in the conceptual stage about a year ago, called the Virtual Server where they would deliver electronic textbooks in a local environment and it would be course-packaged material. America Online also has an experiment going on with Simon & Schuster's College Division to deliver course materials into the classroom.

M: [inaudible]

Tristan Louis: The question is, essentially what is the value of advertising on-line if I understand it well, and what should we do to make advertising work? From our point of view we are hooking up to the Internet product, to Web sites talking about Internet products. Now, I can't go in and tell you that you should advertise your product in this way and you should design your ads this way in order to make them work; that's the work of the agency or the work of your advertising department. What I can do is say, "Okay, if you give me a banner that's good enough and you buy a position in this particular area that is of interest to your public, I can make sure that people will get into your site."

When you pick up a magazine, do you actually think, "well, I wonder how efficient this is?" When you watch a TV ad, do you think, "does this work?" When you listen to a radio ad, do you ask, "does this work?" That's a very big demand on us to ask us to essentially sell your products for you. We are not your marketing department, we're just an advertising medium. A new one, that's true; but at least we can tell you that we are guaranteeing you an audience and that this audience will get to your site. We can actually tell you how many people asked for more information by just clicking on that link.

Patricia Sabosik: I think that's a very good description of where we are today in advertising in the early stages of an interactive medium. But as we move forward there will be more clever

advertising models that will come on the Net that are much more interactive, that maybe in the advertiser's Web site. For example, AOL or GNN or some of the other large-volume Web sites will have ads within the site that the clicks stay within that site, and then those logs are reported separately. So there's a lot more interactivity between the content and the advertising.

There are some travel companies that we're working with to do that, and you'd get a lot more information as you drill deeper down into something that is advertiser-sponsored in the sense that it's bringing a different flavor of content into a site that's complementary with the material that's already there. In personal finance, for example, there are some investment services that are paying to have their content merged with some of ours to provide a particular point of view.

And you're absolutely right about a specific audience; there the value of that is based on how targeted that audience is as opposed to how many hits are coming through because the hits may be lower, but the response rate would be higher.

M: [inaudible]

Matthew Shevach: I think it's a mix. Most of the big advertisers do have agencies or departments that are doing it. Some of the sites themselves, though, have taken steps to do different types of advertising. *Word Magazine* at www.word.com is one that comes to mind. Initially, when *Netscape 1.1* came out with the server-push/client-pull, it was actually flashing up ads when you moved from one section to the next. So you would be in a section, you would click on a button to go to another one, a whole screen would pop up with an advertiser's name on it. And then the advertiser would have a smaller position on the next page. I thought that was neat, but of course there's some limiting factors there for people on a 14.4 modem, and even that's going to add a lot of time going between pages and will really make them angry.

But I think you're going to see things like that starting to evolve, as Pat was saying. I think that burden will be obviously mixed between the site you're on and the agency or department within a company, because you're going to have to cooperate on how you're going to link up those technologies.

Tristan Louis: I'd like to add also that there's a lot of new tools coming out, the most prominent of which is Java, de-blocked by Sun Microsystems, which make an ad a lot more appealing. I'm sorry, but if I see an ad just rotating around my screen when the rest of the screen is very static, I'm going to click on it because I'm going to be intrigued by what's behind it and what else they have to offer.

That concludes this program. For more information about other recorded programs, please call Canyon Interactive at (818) 879-1151.

INTERNET PUBLISHING SHOULD PUBLISHERS JOIN THE PACK OR STAND ALONE IN CYBERSPACE?

MODERATOR

Bill Washburn

Senior Vice President, Internet Business Group, Mecklermedia

SPEAKER

James Outman

Vice President/General Manager, At-Home Division, Information Access Company

James Outman: I think we can get started. I want to, in a sense, apologize; I very slightly changed the thrust from the advertised title. I thought it might be a little presumptuous of me to try and answer the question that I originally raised, which is whether publishers should mount their own Web sites or pursue some other strategy in partnership with other players on the Internet; obviously the answer is that it is going to vary tremendously from one publication to another. I thought it might be a better use of our time this afternoon to suggest some of the questions and influences that publishers might want to be fairly clear about before they proceed to action.

One of the questions that I am curious about is why you are all here. I expect that some of you see an opportunity to take advantage of the Web or the Internet, and I expect some of you may also see at the same time a threat to your existing publishing activities.

Some people may think, "well, this an opportunity for a product line extension in publishing." I actually heard someone earlier say, "well, you need a presence on the Web." I really didn't hear the reason that he gave for that, but clearly there is a sense that, "everyone else is there, so shouldn't I be too?" I think all of us share this sort of conviction that, in fact, the Internet and/or the WorldWide Web is the next mass medium.

No question that the conference program overall shows that there are many aspects of the Internet that are interesting to people; partly as a technical phenomenon, there are a lot of questions of how to do it. I think it's a little less clear, but nevertheless true, that the Web is also an economic and social phenomenon.

So far tool suppliers like Netscape Communications or on-ramp providers have discovered successful economic models in selling those tools to people who would like to publish on the Web. Information publishers, I think, have been less successful so far in finding successful business models in using the Internet or the WorldWide Web, although they have found a fascinating, exciting, possibly profound social phenomenon in which even elementary schools have now become publishers on the Internet.

I think the best course of action — or several actions — for a publisher depends on how you view the Internet and its relationship to your existing business. Is it a product line extension for a print publication? It's a different manifestation of your print publication; it's an opportunity to extend your franchise into a new area — research, for example — or it's about extending your brand into a new medium. Maybe it's a unique new publishing opportunity... Or none of the above. Of course, these are not mutually exclusive; publishers don't have to necessarily choose one to the exclusion of the others. It strikes me that much of what publishers are doing today on the Internet is in the nature of an experiment in one aspect or another of digital publishing; and while I certainly agree that experimentation is necessary, in order to find the model for success I also think we can all save a good deal of time and money by thinking and talking about the likely elements of success or failure.

What's tremendously exciting in the 90's is seeing and participating in what we just heard described as an emerging new mass media — or is it a mass medium? Certainly the

Internet and the Web are emerging in some similar ways that television did 50 years ago; and I presume that most of the people attending Internet World are looking to take advantage of this new opportunity — not necessarily a business advantage — on the Web.

And like television and radio before that, the Net is attracting a fascinating combination of established players, older media and newcomers who see the very low cost of participating in the “next big thing.” The mix of participants is tremendous; there are people from the world of academic publishing alongside people from the world of computer gaming. Television networks are in the game, alongside magazine and newspaper publishers, individual contributors, authors, and of course advertisers.

Some view the Net as a possible renaissance for distressed distributors. I’m thinking here of libraries, for example, who are looking to regain patrons and extend their franchises and their information hub for the next generation, as well as segments of the media that are seen as hurting economically, such as newspapers with really unbelievable price increases for newsprint and declining circulations, especially among Generation X.

Eventually — and probably sooner than later — the winners in this new media will begin to emerge from the field and there will be an inevitable shake-out. Some plans will pan out, some will not; and those who have action without a plan will almost certainly be watching from the sidelines.

One way that I find useful in trying to understand the business opportunity afforded by the Web is to think of every media as being structured as a result of a push/pull tension between three entirely independent forces: technology, society and economics.

The fact that print and broadcast successfully coexist suggests to me that in fact the Web, if it’s to become a mass media, will take its place alongside the existing media, not in lieu of any one of them. And while I can’t speak to the long-term prospects for newspapers or magazines or even television, I doubt whether the Net will simply step in and replace any one of them. I’m not sure that we’re seeing a large migration from existing mass media onto the Web, wishful thinking notwithstanding. The reason is simply that the Internet is likely to emerge, if it does, as a unique resolution of the tension among these three forces. Obviously the Net is going to effect the existing media, but not in necessarily obvious ways.

For instance, who predicted that the impact of television on newspapers would be to push papers to publishing in the morning instead of the evening? And that influence wasn’t strongly felt for at least 25 years after the beginning of broadcast television networks in the 40’s. After all, we’re all basically competing for people’s time and money, neither one of which is increasing at anything like the rate of expansion of opportunities and [inaudible] on the Web.

The rise or fall of any particular publication, or even [any] media, will depend more on that media industry’s unique blend of these three factors: economic, social and technology.

Technology created the Web — the Internet, rather — and more specifically the WorldWide Web. And it’s technology that is pushing the network, just as it did in the case of printing, or with the invention of steam power [inaudible] presses in the 1830’s, or in the early years of this century with telephone, radio, film and later television.

But technology does not act in a vacuum. There are social forces, including government, and in general, people’s attitudes, desires and fears, that react with technology in order to define the nature of the medium. But consumers don’t like the technology, or they view it as a harbinger of something harmful or undesirable. They want to adopt it, and they might even insist that the government regulate it. There are plenty of people, especially in Washington D.C., who quite benignly view the Internet technology as a kind of public utility — rather like the improved highway system — and [believe] the government ought to fund it and control it. In fact, the Internet wouldn’t be what it is today if it weren’t for that view, and it’s still quite prevalent on the Net today. Look around at the contributors and you’ll see a large number who

insist that the Net should resist commercialization and continue to be free — which is mostly to say tax-supported. Many of these people seem to believe, I think somewhat naively, that government funding will come to the party without it's evil twin of government control.

And there are economic factors that tend to effect the development of mass media that are quite independent of either technology or social attitudes. Economics strongly influence how or even whether a given technology will turn itself into a business opportunity. The eventual nature of the Internet as a mass media will reflect the influence of all three of these factors interacting with one another. In short, never mind how cruel it is; if the economic and social forces are not in alignment, it won't happen.

Some people fear, and perhaps some of you believe, that you understand the Net. This is a good thing, because for me, in thinking about the Internet as a form of media, it seems to me at this stage that I see all three of these factors as very much in play. I see anecdotes about what seems to be successful and what people are doing as experiments, but I don't see any clear evidence of formulas for success.

So in my ignorance of the outcome I tend to be skeptical of people who talk about using the Web correctly. Whether they're talking the technical sense, the economical business sense or the social sense, I don't think anyone knows yet what's correct or successful in publishing on the Internet; although I suspect that that sort of claim is pretty good advertising for consultants. And after all we all came here for answers, not just for questions.

My own sense is that there is a good deal of experimentation going on, but on the part of publishers and on the part of advertisers. The social and economic aspects of the Web have not yet been heard from, even as the new technology races forward in some amazing and very cool directions, directions which could change the fundamental technological nature of the Internet.

Lets just talk about the technology for a second and try and understand how it might impact the development of the Web as a mass medium. In thinking about the key technical aspects of the Internet there are three things that I need to talk about; and I'm not going to mention the words HTML or Java.

The first is the leading crusade of our time: media convergence. Partly this means that everything is coming together in one place and you can technically more or less watch television over the Internet, or you can talk on the phone, or you could read a magazine. The conversion also means, especially for publishers, that traditional boundaries between different media have effectively disappeared. In the pre-digital world printed books or magazines didn't have moving pictures and video didn't present words to read. Video could not really present the kind of detailed information — I'm thinking of a chart in *PC Magazine*, comparing a variety of laptops, for example, — that magazines excel in. And on the other hand print really lacks some of the power of video to tell a story.

In the pre-network world a magazine publisher competed with other magazines in a particular market segment and only secondarily with, say, broadcast or newspapers. There was some overlap, but less and less over time. Magazines that didn't understand that don't exist anymore; although not in the original form, I'm thinking of *Life* magazine in the 50's, which thought it could compete with television. And *Life*, and this sort of broad-circulation magazine, eventually gave way to a publishing model epitomized by, say, Ziff Davis, which found some advertising-oriented and community-oriented communities that it could serve.

So over time the boundaries between different media became pretty clear, you knew whether you are a print publisher as opposed to a video producer.

On the Internet the technology now makes that less clear; and regardless of the level of competition the real competition was, and still is, for people's time and money. Still, we all understand the difference between a magazine and a TV program and a telephone conversation

with a friend. The content could be more or less the same — the war in the Balkans, or even the coolest development on the Network — but the context of that is to say a print publication or a television show or a telephone conversation was different. The information was presented quite differently, and the consumer's relationship to the media is quite different — more or less involved, more or less passive. These distinctions are not clear, and in fact the fascination of the Internet, and especially the Web, is the way technology allows a variety of presentations to be blended into single sites. And of course let's not be deceived into thinking that the technology is a done deal.

Everyone can see the possibilities of broad bandwidth into the home, to say nothing of developments like Java — even though I said I wouldn't mention that word. The speed with which broadband arrives on your desktop — thereby enabling video producers to really join print publishers on the network — is being determined today more by the social and economic factors than by technology, because we know that the technology is there, but the economical and social factors are not. At least not yet.

Conversions have some very practical impacts on a publisher. For example, a publisher or a producer from yesterday basically packaged creative content for an audience, and you had to take the package as presented. Today the technology enables your audience or some other producer to unbundle your package and create his or her own custom package. On a simple level, this means using filtering software or search engines and the like to assemble some unique packages of related information — say about news from multiple sources — all of which are now interconnected by the network.

Should publishers therefore think of publishing smaller packages, like individual articles instead of larger ones? There is clearly an opportunity on the Web, but one that may require some other integrator or aggregator in order to take full advantage of it.

The new Internet packages may combine print, video, sound, and graphics. As a publisher or producer, do you have the expertise to provide and combine these elements? Or should you let your customers or some other Web producer use your creative content in ways that you effectively can not? And of course your customers can also misuse your content in ways that you may not be able to control; but that's another question.

And by the way, there's clearly a major social question of whether the mass audience wants to rule their own. There's plenty of evidence that this interest is only a small group of upper-end consumers, which might indicate that the Web is, after all, not destined to become a mass medium.

Who's going to succeed in this world of convergence? Is the system of new media simply a conduit for all sorts of media producers and publishers lying down together like the lion and the lamb? Or is it just combining elements from the old media and cool Web sites? Or has the combination somehow bred some new species all together?

Maybe Web sites have [inaudible], instead of evolving from the dinosaurs of the printing press. I don't think we really know yet, and based on what we can see on the Web today some print publishers believe the Web is about making still photos move; some Web publishers think it's about the revival of the telephone party line, and some electronic publishers view it as a distribution mechanism or an [inaudible] to an existing medium, a way, for example, that a radio station can present program information, or have new electronic print data to their existing electronic data. Who's right? The technology won't tell us; it just raises the questions and offers the possibilities.

Connectivity is another cliché of our time, and is arguably what the Internet is all about. It is certainly something a publisher needs to think about, because it will have a big impact on the nature of your product, and it will have a major impact on both the social and economic aspects of the network.

Within a single medium like the telephone network, connectivity has always been critical. But the connectivity was between individual users, one-to-one communications. The Internet enables the other three forms of communication, one-to-many, many-to-one and many-to-many, and it allows individuals to take advantage of all three at very low cost. One of these forms, one-to-many, has long been the province of publishers and producers; now it's available to anyone for \$10 to \$20 a month. By enabling connectivity, the Net seems to demand connectivity.

In the case of the WorldWide Web, suddenly it's possible — and therefore critical — to connect your Web site with others. This is something publishers and producers never worried about before, and it's a capability that tends to blur the distinction between one publication or Web site and another. The Web seems to be just that, a seamless Web of pages or sites, no one of which has a beginning or an end. What implication does that have for a publisher who's used to a front cover and a back cover?

As you know, there's a whole industry of people creating sites that are mostly comprised of pointers to other sites. Internet consumers expect to be able to jump from one site to another related one, including — or perhaps most especially — to sites put up by your competitors, but by entirely unrelated publishers. This is a public service, but you as a publisher are expected to provide it because the Web enables it.

Interactivity is the third leg of our three-cliché technical platform here. Quite obviously the Net is not a one-way medium, like publishing or broadcasting; it's two-way. Readers and viewers want to talk back, don't they? Actually there's not much evidence that large numbers of consumers do want to talk back to their televisions, or even their books. Some do, and for them the Net is a great thing, because the technology enables it. But more people have made major profits from one-way media than from two-way.

On the other hand, people like to talk on the telephone; the number of long distance minutes sold by long distance carriers has almost doubled over the last decade. So it may be that people do want to talk to each other. What does this mean for publishers? Does it mean that your readers become your contributors? What does that imply for a publisher who traditionally had been the gatekeeper or "getter" of information?

Indeed, what is the role of a publisher when his or her readers are arriving without the benefit of editors? Indeed, for some services these conversations, which are searchable, are in fact a form of public publication in and of themselves.

Perhaps more importantly, is it necessary to use this technical capability just because it exists? This is clearly an area where social expectations will play a huge role. Successful magazine publishers in particular have long realized that they were the focal point for virtual communities of people with special interest. Now the Internet is challenging publishers with its greater capability for members, or great members of virtual communities, and enabling them to find each other and interact with each other — hence my allusion earlier to the telephone. Would you rather read a review of a new computer in a magazine, or talk to someone who owns one? If the answer is you'd rather talk to someone who owns one, what future does that imply for magazines in the computer era?

So I think publishers need to consider whether they'll still be able to be the focus of these communities, or whether they need to find a new relationship with the virtual communities that helped create it in the first place — but which today now exist on the Internet as newsgroups.

And this I think lies at the heart of the question of whether a publisher should try to stand alone on the Internet, or what we think is the role in the world of Internet Communities.

I think the Internet may be the most valuable thing on earth, created by man, that no one owns — not even the government. At least let me admit my ignorance as to who owns it; I

have some understanding that the components of the Net are indeed owned by someone, by corporations who bought the servers and the gear needed to hook into the Net, or by government and not-for-profit entities like universities who contributed vast quantities of hard disk storage and intellectual property at no incremental charge to users. And I know the Net is regulated by a voluntary groups of providers and users; but no one seems to own the thing, and that makes it quite different from traditional media.

In the case of broadcasting, clearly governments claim ownership of the spectrum. In the United States the spectrum was given to private interests by Herbert Hoover when he was Commerce Secretary in the 1920's, and today the so-called public spectrum is traded among private owners for millions of dollars. The telecommunications network is also privately-owned in this country, although more typically publicly-owned overseas, and with the connivance of the government. In this country the owner of the biggest telecommunications network traded control of the network for a government-sanctioned monopoly — of course I'm talking about AT&T — and until recently the concept was that of a common carrier. The phone company let anyone transmit anything over its network, in exchange for a monopoly; AT&T itself transmitted nothing. That model has changed profoundly, with consequences that I don't think we really understand. I expect the Internet will be the focus of much of this change, with the two big carriers, MCI and AT&T, now beginning to play a new role as information providers.

Emergence of both MCI and AT&T on the Internet as content providers is just the most recent — and perhaps the most dramatic — example of how society, here in the form of government regulators, can impact the technological and economical aspects of a medium. As actual perspective players in the new medium we need to keep an eye on how government regulation — or in these days, deregulation — will change the economic landscape.

The issue of ownership arises in a different way as well, in terms of intellectual property, as it takes on a whole new dimension on the network. In the old world you had to be wealthy — as in the case of the corporation — have access to the means of distribution, and then there were effective ways of controlling intellectual property. But in the case of the Net you don't have to be rich to distribute intellectual property, even if it's someone else's intellectual property. When your customer uses network technology to de-construct your package and create his own, who owns what, and what is the granularity of ownership?

As we know, the nature of mass media has been generally towards concentration. This is largely the result of economic forces that say successful publishers will move to gain as large an audience as possible for economic reasons, thereby creating economies of scale for themselves and the ability to crowd out smaller, less successful publishers. Advertisers, of course, have been active participants in this; they'd much rather buy one add in one magazine than have to buy multiple adds in multiple publications.

I realize, of course, there is still great competition between the television networks, whether you count just four, or whether you include the many cable networks as well; but regardless of how many TV networks you want to count, the market share of the top four dwarfs all the rest.

A similar concentration exists in the newspaper industry, where we generally see only one paper per city, where once there were many. Concentration is less pronounced in magazine or book publishing partly because there are many more independent market segments. But within segments — I'm thinking of, say, computer magazines, at least the segments that I'm acquainted with — the role the concentration generally holds.

But part of the reason for media concentration relates to the cost of production and distribution. It's enormously expensive to produce a film or a TV show or a new magazine. It's equally costly to distribute it, especially when you consider the cost of marketing. The gamble, for the most part, is that there will be a concentration of consumers who will make this

worthwhile and which can attract advertisers to help pay for it. Of course, there are exceptions; newspapers and magazines tend to proliferate much more than television networks, and books even more so. Books, of course, are the other tension, because they're not ad-supportive. I think the Net today, or the Web, certainly seems to be a bit like this. The cost to producing a Web page is within the reach of school kids. Does that mean that publishers will be competitively disadvantaged if it costs them much more to create quality sites on the Web? Or will the concentration of the market that characterizes media sooner or later take over the Web as well, as higher-cost, higher-quality pages attract all the users?

And finally, distribution. Distribution is probably the costliest aspect of traditional media; it is certainly the big barrier of entry, and it's the aspect of the Internet publishing that attracts so many entrants. In the traditional media, distributions help push along concentration, which in turn makes mass media very profitable. Successful distribution means many people are consuming a limited number of products and the rewards can be huge, whether the business motto is "advertising pays" or one in which "consumer pays," as in the case of movies and books. By the way, I think the issue of who pays, advertisers or consumers, has a huge impact on distribution. As I said earlier, advertisers generally pay for large numbers of viewers — or readers, at least — at the time they are going to buy their products.

This in turn creates a case where concentrating the audience in a small number of outlets is a clear advantage for the advertiser. Consumers, on the other hand, have many diverse interests, and if they're paying they will support a diverse number of publishers. This is reflective in book publishing, which offers a huge number of new titles each year, many of which sell really relatively very few copies. And still there are book publishers who can make an adequate living on small volumes, and the distribution channels generally supports this.

The economic of "consumer pays" media have other characteristics as well, such as the "blockbuster" model that sustains Hollywood and, to a more limited degree, book publishing; the blockbuster model being, of course, that your profits really depend on the one or two big hits, having spread a large number of potential movies out on the market. How is that model going to apply to the Internet?

How does the Web effect distribution? I think the first question is whether the Web will emerge primarily as advertising-supported or consumer-supported. It could emerge as both, but then we'll actually have two different mediums perhaps using the same technology.

And I think if you're a publisher it's useful to understand which of those models you want to go for. Of course right now no one is paying, by and large, which will become a problem sooner than later.

If advertising support does become dominant there will be a tendency towards concentration on the most popular sites. Some publishers — I'm thinking here of *Time*, in the case of *Pathfinder* — have already concentrated a great deal of content into a site that attracts very many hits on a given day.

But the Internet has thrown the advertising-oriented publisher a curve ball, because it turns out that advertisers can distribute their information themselves — recognizing that advertising had always been the combination of entertainment and information. The Internet advertisers need the packaging. Does [it need] distribution offered by publishers in the print and the broadcast world? Possibly not. On the other hand, can advertisers continue to attract consumers to their sites without the content offered by publishers? We really don't know yet.

The Internet also has some curve balls for the "consumers pay" model. If it succeeds, the Internet will continue to support a wide variety of small enterprises; but we still await a clear winner in the technology to find a way of conducting secure transactions over the Internet, so the consumers can pay per site and feel confident and comfortable in doing so.

I think that as a publisher this is the key question: who is going to pay? It's not yet been answered definitively in the case of the Web, but the outcome will certainly determine whether the Internet is a business opportunity for you, and just what size and sort of opportunity it becomes.

So the network changes all the assumptions that the media businesses base their business on. Production costs are low or high, distribution is cheap or expensive. Maybe the Internet won't be a media business model at all; as a medium, perhaps it's really a successor to the telephone network, allowing millions of individuals to become publishers with very small audiences, possibly as small as one. Although I think this is an unlikely outcome, I think it's a possible outcome in a media that may end up with a variety of outcomes.

Finally, society is a factor in determining the nature of a mass media. In some respects the social aspects of the Web may prove to be the most important of all. Certainly they're the most difficult to predict, and they're the most difficult to influence for any one publisher or vendor.

I think, to some extent at this conference, that there's an unspoken assumption that "if we build it, they will come." The assumption is that we will be able to cross that chasm; but there's a whole graveyard of technologies out there that never actually did cross that barrier, that looked very promising at the up-slope of the bell curve and then fell into the gap between "early-adopter" and "early-majority."

Let me just review three points here. First, government regulation. The government effectively created the Internet, funded it, and then dropped out. Is it going to last? I wouldn't count on it. By the way, this issue is not as clear-cut as you might think. I'm willing to trade my libertarian credentials with anyone, and certainly I have no interest in seeing Senator Exon, to cite one, regulating the content of the Web. If having pornography available on the Internet is the price we pay for freedom to have anything else we want, then so be it; you don't have to download those pages, and there are ways to protect young users. After all, we apparently solved that problem of protecting young users when it comes to the convenience store market, in their particular selection of periodicals literature.

But on the other hand, how do we feel about having, say, AT&T control the Net, now that AT&T is — at least in one of its manifestations — an information provider? Arguably there have been advantages in government regulation of the telephone network, and for that matter its publicly funded programming on PBS, which has more often than not broken through the mass market programming tastes of privately-owned television networks.

Secondly, market psychology. The very promise of the Internet is a cornucopia of information and material unfettered by some of the regulatory and economic constraints of existing media. Nevertheless, the public is not swarming onto the Net in the way, for example, that the public swarmed onto VCRs. Indeed, the mass audience has never swarmed onto narrow-interest publications. There's a reason that mass media is the way it is. Most people like what's on the mass media; you know, QED. So although the impediments of getting on to the Net are significant, as a consumer it takes a \$2,000 receiver, which in turn requires traveling up a moderately steep running curve. But I think this explanation for the lack of mass market consumers on the Net today consistently demonstrates the public's appetite for mass consumption.

The most vexing question about the Net is whether it's destined to remain a domain of a relatively small intellectual elite, or whether it will indeed become a mass media that will support advertising and major funding. Time will tell, but it hasn't told yet.

The other side of this question, of course, is the rate of adoption; or to put it another way, how long should we wait to answer the previous question? The personal computer is about 20 years old, and about one-third of households have bought one. Television, on the

other hand, over its first 20 years, gained enormous penetration — much, much higher over the same period of time. So does that suggest the Web may not be a mass media after all? And if it isn't, how should publishers relate to it? Put it another way; if you published a magazine, or a newspaper or newsletter, how many of your subscribers are now on the Net? When are they likely to get on to the Net? I don't think that any successful publication, whether they be broadcast or print, could possibly afford to drop their print or their broadcasting issues today and exist solely on the people who are on the Internet.

So, getting back to the advertised title [for this session]... I think some of the questions that publishers need to ask themselves about going onto the Web, as they rush to do so in very large numbers, is whether they have an economic model that fits with the technology model of the Web. Does your economic model allow for interactive users who may de-construct your products in order to create their own? What about the social model? Who's to be the economic and technical model? Will there be a lot of people who are willing to adopt Web technology? Will your readers or your viewers be among them?

What's your expectation of the eventual model? Is interactivity going to be important to people, or is it only important to a small number of people who are already there?

And finally, what's your tolerance of risk? This involves the risk not only that no one might come to your site, but that also you might spend considerable time and money only to fail in this new media. Actually, of course, my personal hope is that all publishers put up free sites as soon as possible and develop a very large tolerance to investing without return; I personally love surfing, and I think free stuff is absolutely great.

Finally, a very brief ad for Information Access, which is the company that paid my way here. We have put up a site, my skepticism notwithstanding, that's called *cognito.com*. It's a research service aimed at students; we see it as a downstream application of content that works, because there's so much content concentrated in one place on *cognito.com* — several hundred magazines and several dozen reference books. We're quite eager for publishers to join us as publishing partners in the venture, and I'd be delighted to talk to anyone who is interested in doing so afterwards.

Thank you for your attention and your patience.

INTERNET LEGAL THE LAW OF CYBERSPACE: AN OVERVIEW

Wayne Martino: Just to make sure everybody knows, you are at the legal seminar, "The Law of Cyberspace: An Overview." Let's start with just some administrative matters. There are some handout materials that are just about gone that were in the front, to the extent that you wanted to get them. I understand that all of the sessions are going to be put on CD-ROM and may even be put up on the Web, so those materials may also be there.

The sessions we have scheduled for you today are threefold. In the morning there is an overview session where we will be covering privacy and pornography. Everybody can go back, you've now missed the handouts, they're all gone. We'll be doing privacy and pornography first, and that will be done by Lance Rose, who will be doing computer crime. We'll have a ten minute break and then we're going to come back and do copyright and trademark, First Amendment in advertising and then an on-line lawyer from AT&T is going to be here also. The last thing that they are reminding me of is there will also be audio cassettes available for you.

Just to get a flavor for who is here — how many lawyers are present here? How many people have practice in the Internet or are they just thinking about it? Okay, about the same. In preparing for this, I came across this cartoon which I think is particularly appropriate, and it's interesting for a lot of different reasons.

You have a fortune teller here who is telling the fortune, and I think that it raises some very interesting questions, the first one being "who is the fortune teller?" Is it the lawyer? Is it a lawyer who now wants to know about this new medium because they have been presented with an issue by a client? Is it a judge who now has been faced with a question and doesn't know anything about the medium, and now has to determine how he's going to deal with it? Is it a long-time, on-line user that says "The law of cyberspace? There is no law. This is the wild, wild west, we don't need law here." Or is it an academic who now is writing about this? And the worst thing of all is a legislator who probably doesn't even know what a laptop is, let alone the Internet.

You then come to "who wants to know, and why?" The person sitting across [from me], you can obviously tell, was very nervous. Why did they want to know? Well, it could be the same people who supposedly were the fortune tellers. The lawyer may be nervous and be going to somebody else to get the answers. The on-line user may be

going to a lawyer. All the same people who could have been the fortune teller could also be the person who wants the information... and why do they want to know?

Well, they want to know for a lot of different reasons. Maybe there is some additional factor that has now come into this, for example; there's a new user that's here, or someone from the investment community who is now going to invest and they say, "Well, I want to know what the rules are that are going to govern my behavior."

So, you could tell that this person was nervous. Why was he nervous, and should he be? If it was a lawyer or a judge or a legislator, they may be nervous because they don't understand the technology or the medium. They hear about the Internet, they see it in the newspaper, but they don't understand what this phenomenon is and they're not sure how to deal with it. It could also be that they are uninformed about the law. They're technologically savvy, but they don't know anything about the law and they're now interested in doing that. It could also be that they know that there are many questions in this medium but there's probably as many questions as there are answers.

So the question then becomes, why do we need the laws? I think what is happening right now in the industry is that the Internet is growing up. Right now it's in its embryonic stage and it's growing up, and what is fueling it right now is commercial activity. That commercial activity has a culture that says we want to know what the rules of the road are so we can govern our behavior. There must be predictable results to the extent that we put things on-line or our people are on-line, in terms of how we're going to approach this. There must be consistency of results. There shouldn't be a situation where in one circumstance the answer is one way and in another circumstance it is different. And this is all sort of being generated because of this commercial development.

The next question is, how are the laws going to be formulated? What happens here that I think is important is that people have to understand the custom and the culture and the context and the capabilities of the Internet. If you don't understand that, because this is a new medium, it is difficult to formulate laws or to apply principles that are going to make sense.

What you need to do is, after you've understood that, you have to look at existing legal paradigms to understand what things may be similar. That doesn't mean that something that may be similar is the end of the analysis, but traditionally the way that the law has grown up is that when it deals with new technologies it will look to see what things are similar and then apply those principles, or may apply those principles. Just because something may be similar or seemingly similar doesn't really end the analysis if you don't understand the rationale and the objectives and the evolution of how that law was developed.

Again, it is very difficult to understand and apply that to this context. Once you've made that analysis to determine if the existing laws apply or whether you should create new laws many on-line users — not many, but some — on-line users would suggest that there shouldn't be laws or that there should be totally new laws. I think that the way the law will develop in this area is not to throw out all of the old laws; it will evolve over time, and the common law will develop in a way that will make this all make sense.

As you look in the area to determine what the law is, which is why everybody is here, you will note that it is very much in its embryonic stage. It is probably much farther behind the development of the Internet as an industry from a legal perspective. There are a very limited number of cases and statutes out there. Probably, the fact that there are few statutes is a good result as opposed to a bad result. The record you'll see

for people is very — for legislators and all of the actors in this area — is quite mixed. In the legislators you have, for example, the Exon Amendment, which I'm sure Lance Rose will talk about, that has the potential in some circumstances to really inhibit the growth of the Internet. With respect to the courts, you have courts that are coming out on very [different] sides on the same issue.

For example, one recent case that has come up is the Stratton-Oakmont case [which] dealt with the liability of a system operator for content that was posted on its system. That case has recently been withdrawn. We don't know where the opinion is going to go but the decision there seems to be — besides, again having the potential to limit the growth of the Internet in terms of how it can develop — it also is directly contrary to another decision in the *Cubby vs. CompuServe* case. What you are going to learn today is that there are many questions out there and that there are some answers; but what's happening is that the law is developing in the area and it's developing in a way that will hopefully make some sense and provide some rules for everyone.

What is important here for people who are active in the industry is that you have to have the goal that is going to promote and not inhibit the growth and utilization of this industry. The industry is growing very, very quickly. There are tremendous pressures on it from legislators who are sometimes having a knee-jerk reaction to what is going on.

I think the article in *Time* this summer was a good example of that. When they had the Oklahoma bombing, all of a sudden there was a lot of interest in the fact that you could pull this material about how to make a bomb right off the Internet. What people failed to realize, or many people failed to realize is those materials are available in your public library, but because it is the Internet and the media has really become attracted to it, it is now going to a position where every time there is a case that we see in every day life but it has the Internet attached to it, some actor in the legislative role feels that they've got to propose a bill or some other mechanism to deal with the problem. I don't think that's the way the law is going to develop. It is probably more likely to develop through the common law which will be an evolutionary process and will be a process that will allow for people to understand the medium.

For those people who are long time users I think that one critical element is that they have to be vigilant in making sure that is what's done here with respect to the Internet does not destroy it. I mean, the potential for laws in the Internet again have the potential to both promote or to inhibit the growth and if the long time on-line users, or even the new users, don't communicate to legislators or courts or even the lawyers who are representing them what the Net is and what it means, the potential is there that it will be destroyed.

I'm going to turn this over to Lance Rose. Lance Rose is a partner in Lewis & Roca in Phoenix. He is the co-chair of the intellectual property department. Lance is a long time on-line user and prolific writer in this area. His book, *Net Law*, which is published by Osborn/McGraw-Hill and which is available upstairs, is a terrific overview of the law and I highly recommend it. So I'll turn it over to our first fortune teller, Lance Rose.

Lance Rose: Thank you. Privacy and pornography are a pretty big chunk to bite off and we don't really have time to get into how the whole thing works, but I was thinking about how to talk about this meaningfully and give a sense of stuff that is happening now, and also a sense of a little bit of the history. And there are a couple of recent events. It occurred to me there's a couple of recent events that many or most of you may have

heard of, that actually bring up both privacy and pornography angles, interestingly enough, which I hadn't even suspected. Wayne gave me a topic, privacy and pornography. Next thing I know, it looked like they come up a lot together, so it will make a nice kind of structure for the presentation.

The first thing I'd like to talk about is Operation Starburst. Anybody hear of Operation Starburst? Innocent Images, does that ring a bell? Okay. Anybody hear about the arrests of a lot of people who were allegedly trafficking in child pornography, many of whom were America Online users? Yeah, we heard of it that way. America Online, I think, is the key word there. This is a very bad PR event for America Online and I think maybe they felt a little bit betrayed about cooperating with law enforcement in that particular instance. I don't know the full story on that.

Anyway, it seems for a couple of years the FBI has been investigating so-called child pornography. trafficking in various kinds of on-line environments; and, by the way, who here has gone into the Internet other than through the WorldWide Web? Great, this is much better than the last crowd I talked to. Everybody was only a Web user. It was pretty incredible. So, apparently — I just get this from the news and stuff — apparently they were investigating for a couple of years, and eventually they went in a one-day kind of shot and went after a lot of people, and the FBI put out a public statement that a lot of these people were America Online users. They made a point of saying that; and they were very interesting events.

This thing has a pornography angle and a privacy angle, so what's the pornography angle? The pornography angle is this whole pornography and child pornography and this raid on so-called child pornographers, and apparently there were sting operations going on. The FBI had people out there posing as people offering this stuff to others, as people who were looking around for it — stuff like that — and luring all kinds of people in, according to what would supposedly be their own proclivities, into these relationships that would lead to their being under suspicion.

Child protection on-line is actually a somewhat broader subject. I mean, there is pornography but there is also this child protection thing which I'm sure we all see every day in the news at this point. It is a very big deal. Child pornography is just part of it. We have other major things that have been in the news.

As Wayne mentioned, there is the Exon Amendment or the Communications Decency Act which was one of a number of on-line, adult material-type regulations that were recently voted into law by Congress; although we're not certain yet what form. There was a cyberporn... *Time* magazine had a cyberporn cover story by a fellow named Marty Rim which was largely discredited. Much of the credit for the discrediting goes to Mike Godwin who is a regular writer for *Internet World*, which is a magazine associated with this conference, I guess.

There is software out there. There are people looking to make a fortune in software that will let parents keep their kids from getting at on-line pornography or indecent material such as *Surf Watch* and there's others — *Cyberpatrol*? Is that one? These great names. There is discussion about new laws against on-line pedophilia. As many of you might know, a lot of the universities are shutting down access by students to sex-oriented news groups, that's been going on for a couple of years. One particularly interesting one I like from the child pornography — I don't like it, I just find it of interest, I like it in that sense — is this proposal by Orin Hatch to extend the child pornography laws, which is really kind of neat in concept because it shows you how screwy legislators can get.

Right now we have a structure of three general kinds of pornography laws. We have obscenity laws, which is the really hard core, triple-X stuff; and that's the one where local community standards come into play. If the local community thinks it's bad news and it also happens to lack any serious literary, artistic or scientific merit, it can be obscene if the state law says it's obscene.

Then we have indecency which largely applies in TV and radio so far. That's like the seven dirty words that you can't say... and phone sex services being limited to getting only so racy before they are considered to be breaking the law.

Then we have child pornography and child pornography is not content-oriented, specifically. The obscenity and decency laws are content-oriented. If it is really bad news it can be obscene. If it's kind of bad news and you just want to keep kids from it but adults still have a First Amendment right to get at it, that's how the law works there. Again, based on content, it can be considered indecent. Child pornography goes at the production of the images.

There is this theory that the law is based on that any involvement of children in sexually-oriented materials likely involves abuse of those children, sexual abuse of some form. It is kind of a prophylactic law, so to speak. It's such a bad thing to have this potential abuse of children that you just have this very strong law outlawing any use of kids in the production of these materials, and there was a record keeping requirement making sure that people kept track of the ages and so forth. Well, Senator Hatch and some others have this new theory which is that sexual images involving images of children are tools that can be used by pedophiles and other people who want to lure children into bad sexual things; so now we should have a law outlawing any use or propagation of these tools, these images that can be used as tools.

This is a very strange theory. If you have a picture — it could be a picture of, you know, teenage kids with awakening sexual impulses or something — I suppose it might be used for sex education. If the wrong person gets their hands on it and can use it potentially to seduce a kid saying, look, it's okay. This kid does it, whatever it is, so you can do it too.

Based in this kind of theory — that it's a tool that's really awful — this proposal that's being made that child pornography laws outlaw the creation of such images, so it would no longer be just images involving the use of children in production, but something that might just come full-blown out of someone's head. Some artist could just draw a picture and then, based on the content of that picture — a sexual image involving a child — it would be outlawed. And apparently he says the precipitating event was the fact that you can easily, digitally — using things like *Adobe PhotoShop*, sticking a picture of a kid's head on a picture of, like, people having sex or stuff so you can make it look like the kid is having sex, and they don't like that. It's like another evil of the digital world. It's a very screwy theory. It's really way outside the First Amendment, but there's a proposed bill out there right now. So, there's this kind of weirdness surrounding pornography and on-line computer stuff. And Operation Starburst — I believe that's the name that was given to this child-porn-trafficking thing — is one outcome.

The interesting thing to me here, is that this isn't just something that went on for a couple of years and when it naturally came to fruition the FBI went out and arrested a bunch of people. It so happens that as Operation Starburst, as these arrests were made, as this public statement went out, there were about four or five — as I mentioned briefly before — four or five different on-line porn bills that Congress somehow magically all voted into law, one House or the other, which all have to be reconciled because they partially contradict each other. But we don't have time. Maybe if we have a

question-and-answer here, well, I can't go into all these different bills; but some are lenient on system operators, some are hard on system operators in terms of making them the cops for on-line pornography.

And while Congress — and they're still in the process of doing this — was preparing to figure out how to reconcile all these bills which could lead to a more harsh or a less harsh kind of regulation of on-line pornography, there was the announcement that there are zillions of child pornographers and you find them on America Online. This is sure to influence the thinking on how harsh the law should be. That's, in my mind, not a coincidence at all. I think it is, in fact, exquisite timing.

But there is another point to this. This is the privacy angle which really, I don't know how it affected others but it really took me by surprise. One or two weeks after Operation Starburst and the big PR event from the FBI, the director of the FBI went to some security conference in Washington and gave a talk on how the government really should be making it so that any of us who want to use encryption will have to give a means of decoding our messages to the government or [to] some government-approved agency; so that if agents want to take a look at what we're talking about — and upon proper process, whatever that is in a given case — they could get the keys and look at what we're talking about, assuming they could find where it is. So, this is interesting. So, I'll use this to very briefly do a little historical thing, very brief.

Encryption is self-help privacy. It is a way of securing your privacy without depending on anybody's laws, without depending on anybody to play nice. When you really want privacy, encryption is the way to do it, assuming it is legally available, which it is to you today. Governments, the U.S. government certainly — and they're not shy about saying this — they fear the use of encryption by terrorists and other people like criminals, people who would use the ability to hide what they're talking about to do bad things. This is certainly not an outlandish fear. A lot of people think it's an overblown fear in terms of the kinds of laws that get proposed to regulate encryption, but that's kind of the stance they take.

So, as I said, there is this key escrow proposal which the FBI is now openly pushing, they were kind of privately talking about it for a couple of years, as was recently revealed when a privacy group in Washington, under a Freedom-of-Information request, showed that the government was talking about this several years before they actually admitted they were thinking about it. But now they're openly saying that if people want to use encryption technologies and so forth in this country, perhaps we should have a law that says it can be secret from everybody but the government.

By the way, I saw in an article the other day that the European — what do they call it now, the European Union, European Economic Community? They keep changing the name, but it's a bunch of countries in Europe that are kind of acting together — and these countries led by France and Germany are considering having the same kind of thing, a key escrow in a large chunk of Europe. So this is an international kind of agenda. It's not just the United States crunching down locally to people who like encryption being the bad guy. A lot of countries share similar fears about the abuse of encryption.

So this guy gave this talk, and then to show the need for this ability to crack the code, he mentioned that several images found during this child pornography raid were encrypted. This was Exhibit A in his speech. I was reading an account of this and somebody, apparently he was there, said that someone in the audience asked the FBI director, "Well if the stuff was encrypted, how did you know it was child pornography?" to which he demurred. But you're not supposed to ask those questions. You're only supposed to take the conversation to level one and stop there. Thus, what originally

seemed a well-timed child porn arrest operation had another twist. It's also being touted as one of the reasons we shouldn't have self-help privacy in this country. So it's kind of an interesting connection there.

Okay, that was event one. The other event is a case that was recently started up. It's in its beginning stages, called "Guests vs. Lice," which doesn't really reveal who the parties are. It is a lawsuit by a bunch of users of a Cincinnati direct-dial bulletin board system against the State of Ohio and the Sheriff's Office of Ohio. In the summer of this year, I believe it was either spring or summer, a number of bulletin boards were raided including a fairly large one that apparently had several thousand users raided by Ohio state authorities in search of some pornography.

Raided, the computer equipment was taken back to the office. This is the standard style of investigating bulletin boards. They investigate for a while secretly; then, when they decide they've seen enough, they just grab the thing and take it back to the office. This has been going on, actually, for years. It never got much publicity because bulletin boards have always been such a grass-roots phenomenon, not highly recognized by the normal media. Bulletin boards, for instance, are as big a communications environment as the Internet or large on-line systems. They're on a comparable scale, but they just really never got the press because that's not what they were about — getting mainstream press. They are showing up on the Internet now, the more ambitious ones, and that's going to be an ongoing process. But some of their experiences are very relevant to what the rest of us will be going through. Web publishers and Web sites with increasing functionality that start getting towards being more like bulletin boards — with people interacting instead of just publishing at people — are going to have very much the same look as a local direct-dial bulletin board has today, except, of course, they'll be accessible from around the world.

So there was this system seizure, and there was a civil rights lawyer in the area who found this kind of disturbing, that all these thousands of users... This wasn't a bulletin board — this large bulletin board that was like a porn bulletin board — it was a bulletin board that may have had some pornographic stuff on it and it had thousands of people doing other things altogether, the perfectly innocent things that we know that people do on-line. It struck some civil rights. I don't know the fellow's name unfortunately, but it struck a civil rights attorney out there kind of odd that all these people would have their rights just trampled on in a search for a little bit of pornography. So he filed a class action against the Sheriff's Office on behalf of all the users of the system whose e-mail was taken, whose group activities were disturbed.

So what's the pornography angle here? I mean, obviously it's a State Sheriff's Office going after some pornographic materials on-line. The way they did it is fairly typical of state actions across the country. There have been some kind of notable ones.

I'm kind of curious. Has anybody here ever heard of Tony Davis in Oklahoma City having been arrested and sentenced to jail? Anybody? This stuff doesn't get all that much press. This guy ran a fairly large bulletin board in Oklahoma City and he also sold some CDs and he had a full stock of CDs, a full line of CDs, and a few of them were sexual or adult material CDs. Some of these CDs were also mounted on the bulletin board so that people could call in and download images, and the local police did an investigation. [A policeman] did a couple of buys of CDs.

When they decided they had enough evidence they went in with a TV camera. Out there in Oklahoma City, apparently they do those reality TV shows, I guess the national ones are like *Cops*, so they did one there, I think it's called *You're Busted*. They walk in with the TV camera and they ran into [the subject's] place and they were

arresting him and they didn't let him turn down the BBS. They're shooting a screen where the CD-ROM was mounted and they say, "Here's pictures of people downloading smut," — just great press. They produced their own show and had it shown that they were busting him. He went on trial and the on-line... apparently there was an on-line component and there was a selling physical CDs component.

The on-line component really didn't go anywhere but he did sell a couple of CDs which, according to the fairly conservative standards of Oklahoma City, were considered obscene. He got sentenced. One thing that kind of sticks in my craw over this one is that the CD-ROMs, at least a couple of them, they were described, you know, the titles were given. One was called Busty Babes. You could look in the back pages — I'm not sure you could do this today — but you can look in the back pages of PC Magazine, of all publications, and they were there advertised. Any bulletin board operator — you know, these are regular guys, these aren't lawyers. If they see something advertised in a national magazine that is kind of out there and public, they're to be approached by police if they're doing something wrong. This stuff was being openly sold. He just buys some of this and resells some of it, makes some of it accessible to people on the bulletin board. Next thing you know, he's popped. That's the kind of experience, by the way, that more on-line people will be having as the police become more familiar with on-line environments.

The other interesting one I'll mention here, another bulletin board case just on the way, went the other way — partially the other way. There was fellow in Arizona named Lawrence Chance who was a state trooper who had a bulletin board and apparently had some adult materials. He had his stuff — his bulletin board — taken because of allegations of distributing obscenity. As a state trooper he lost his job, and he lost his pension, just from the fact that he was under suspicion of distributing obscene materials.

The prosecutor went to the Grand Jury twice to try to get an indictment, and the Grand Jury refused to indict because there was a real hang-up on the knowledge issue. He knew these were adult material CD-ROM, but whatever images these people had in mind, there was apparently no prospect that they could show he knew the particular images. These CD-ROMs could have thousands of images — with no prospect of showing that he knew those particular images were on there — the ones that they picked out, that they said were really bad news. It would be like saying, you know, someone buys an issue of *Playboy*, I think most people are familiar with the range of images in an issue of *Playboy*, none of which are obscene. Then they stick an obscene picture in there for a laugh. Is the buyer of *Playboy* supposed to understand? Is this newsstand selling *Playboy* supposed to take the risk that there is one obscene picture sprinkled in among the obviously much less hard-core images? He got off. They just dropped the thing altogether, no charges, no indictment. I guess he got his computer back, although I think he's still out a job and a pension. Last I heard, he was looking to sue the people that put him in that position.

The last thing I'll mention is a privacy angle here. I kind of mentioned it briefly already; when this bulletin board was seized, the private messages and files of hundreds and thousands of people were kind of swept up. We're back in Cincinnati now with this bulletin board — I forget the name of it — the Cincinnati bulletin board — and all these people had their private messages seized and potentially looked at. Now these users in this class action suit are alleging that they have privacy rights under something called the Electronic Communications Privacy Act. Ken's going to be discussing that Act in more detail than I would even want to get into right now.

I'll just mention, for the purposes of this case, that the Act distinguishes between intercepting something while it's being sent and taking something off the computer while it's in storage. When messages are in storage, the rule basically is: if the government wants to get at those messages, if they're less than 180 days old, it needs a warrant from a judge. If they're more than 180 days old, they can do it kind of out of their administrative subpoena and they're supposed to give notice — advance notice — but there are a lot of conditions under which they don't have to. It doesn't seem like they did any of these things. It's not certain yet; all the facts haven't come out; but it doesn't seem like any of these things were done when the bulletin board was taken.

One of the interesting things about the Electronic Communications Privacy Act is that if you have thousands of users each one of those people has rights under that act. So if you take a bulletin board with two thousand users, e-mail on it, private e-mail stored on it — and there were two thousand people whose rights that properly the government should be dealing with before it would maybe even take the bulletin board physically and certainly before it would even dream of looking at any of that stuff. And [the government] should give a reason to each of these people as to why it should be looking at their, or taking their e-mail.

The other issue that came up — the other major claim which is kind of interesting — is the assertion by these users of the bulletin board they have a First Amendment right to peaceably assemble. That's built into the First Amendment. It's not as famous as Freedom of the Press, but we have a right to get together and talk over things — political things and other things. So it wasn't just the private e-mail, it was also group discussions, group interactive situations. When the bulletin board was seized and put out of operation, obviously, all these interactive discussions and conferences and get-togethers stopped on a dime.

This computer bulletin board was supporting the get-together. It would be like somebody came and took this building out from around us and our seats and we were all kind of in free-fall — not in the same place any more. We wouldn't be able to interact very well. That's, in a sense, what happened when the bulletin board was taken away. They are also asserting that that right was infringed by the action against the bulletin board. So in that case — in the Cincinnati case — two questions are: Can government agents ignore the individual privacy rights of thousands of bulletin board users in their pursuit of on-line pornography? And also: Can government agents ignore the rights of thousands of users to congregate with each other in the pursuit of on-line pornography.

So, I know it's kind of fast and sketchy, but hopefully that will give you a flavor for some of the current issues that are happening, a little bit of the history and we'll have question-and-answer sessions a little later on if you want to talk about more specific things. Thank you.

Wayne Martino: Our next speaker is Ken Rosenthal who is a partner of mine. Ken does civil and criminal litigation and he will be addressing computer crime.

Kenneth Rosenthal: As somebody who has practiced in criminal courts for many years, sitting and listening to stories about what's been happening recently, or reading about them in connection with computer-related incidents in law enforcement is troubling, but not totally surprising. I say that because there is an element of, "Maybe it's just in the nature of having a criminal justice system under any circumstances," an element of discretion and of arbitrariness that can seem very unfair at times. There are times when

I think anybody who works in this system says to themselves, "It seems like the people who should get punished are not getting punished and the people who are getting punished shouldn't get punished." You have many areas — as I said, it's partially in the nature of the system — but I think that there are some aspects of trying to apply old criminal laws, established laws, to this technology revolution that just aggravates those problems in the extreme; and I'd like to talk this morning about two aspects of that.

One is the substantive criminal law as it is being applied or has been applied and has been amended and changed, to the Internet and to bulletin board operators and to situations related to that. The other is: What is the law as it exists and as it's been amended? and another is the way it works in the criminal justice system — kind of on the street and in its implementation, because I think that's where, in some ways, the problem is the greatest at this point. Starting with the law, there was a problem and there still may be perceived to some problem, but I think it's mostly been eliminated, with applying traditional criminal law notions to information "property."

Larceny, for example, which was one of the laws that you find — larceny concepts are in the laws that were being applied to the misuse of computers or illegal acts with respect to computers — larceny has some elements, at least traditional elements, as most judges and courts and lawyers have been used to dealing with it, that require there to be, first of all, property and second of all a permanent deprivation of property.

That is, you have a piece of property that the owner has a property interest in and the thief has taken the property and permanently dispossessed the owner of it in such a manner that he is guilty of stealing. Of course, the problem with a lot of the computer crimes that those statutes were originally applied to was that the owner hadn't been permanently deprived of anything; or at least it was difficult to say what he has been deprived of, because the information or the data that someone may have made a copy of was still resident on the owner's computer. The case that some of you, I'm sure, have heard of and that we may talk a little bit more about this afternoon, the Stephen Jackson Games case — or looked at from the criminal side, the [Riggs-Nederdorf] prosecution — involved that type of a situation to some extent.

Bell South Telephone Company had on its computers the instructions for how the e-911 — the emergency phone system — operated. Law enforcement became concerned because they were told a college student had accessed that computer without authorization, had made a copy of that manual on the e-911 system, had transmitted it to another young fellow who was a college student but also published a magazine — *Frack*, I guess, was the name of the magazine — and he, in turn, had put it out over his electronic magazine to many, many people all over the place.

The Secret Service, which is the federal agency along with the FBI with responsibility for enforcing many of the federal computer-related crime statutes, got involved along with other federal law enforcement agents and brought a prosecution. Prosecution was brought against Riggs and Nederdorf under, at that time, a number of federal statutes, one of which was the interstate transportation of stolen property, another of which was the wire fraud statute.

The wire fraud statute, as it has been construed, includes an element of some kind of property, although that property can be fairly intangible. One of the issues in that case was whether [Nederdorf], when he was being prosecuted as the magazine distributor, had taken something of significant value, because the interstate property statute also has a requirement, common with larceny statutes at that time, of a certain amount of value. You have to transport something across state lines that's stolen [and

which is] worth more than \$5,000. It quickly developed in the course of the trial that this supposedly highly secret e-911 document was a document that was readily available to the public by the simple practice of dialing an 800 number that Bell South had available and paying \$13 to get a copy of it.

So, one question was, "What property has been taken?" The second question was, "What's the value of that property? Well the value of that property at most is \$13, if that's the price they're charging the public. That was the end of the [Nederdorf] prosecution for all intents and purposes.

Now Riggs, the fellow who had accessed the computer without authorization, had pleaded guilty, and maybe wisely so, because there was also an unauthorized access to computer count that he had to face under the Computer Fraud and Abuse Act. That is one example of a case where traditional theft concepts, or larceny concepts, don't have an exact fit. They definitely don't have an exact fit when law enforcement jumps to conclusions that aren't based on the facts.

As a result of enactment of a lot of statutes and changing of statutes that weren't originally covering what people thought they should cover, there is now a fairly sophisticated, complete and computer-specific set of statutes on the federal and the state level, that are available to deal with (a) unauthorized access even if nothing is taken, and (b) to address issues of value that are harder to define when you're dealing with these kinds of pieces of property.

The thing I'd like to spend a little more time talking about is what I think is the real problem here — and it's a problem that hopefully can be addressed as time goes on — which is that law enforcement, in enforcing or applying criminal statutes to the computer area, doesn't tend to get involved on the local level; and tends to get involved on the federal level only when you have these highly publicized cases.

It's as if, in a way, the only law enforcement that you have going on in the world of Internet information superhighway transactions are the O.J. Simpson kind of cases — the cases that get lots of publicity because somebody in the relatively small law enforcement community at the federal level, which has the resources to deal with this, sees something that's big enough — or that they think is big enough, or that they magnify into being big enough to pursue, and that there is not a lot of interaction or knowledge between local law enforcement, which is where most law enforcement occurs, and the people who are perhaps legitimate victims of problems with computer crime. And that's a problem that's been addressed.

It's been noticed by the National Institute of Justice and others that computer crime is different; it's more difficult to pursue, so local prosecutors and local police don't tend to pursue it. What tends to happen is it's only these highly publicized and sometimes not really appropriate cases that get pursued by the Secret Service and the FBI when they think there is a point to be made.

The reasons for the problem — or maybe the ways to address it — are several. I've been involved and I'm sure many of you, not only lawyers but business people, are involved at times with trying to get law enforcement to take up a legitimate problem that you have. When the problem is a problem involving complexity, you don't find local law enforcement jumping on the bandwagon because they have enough to deal with, they feel, with regular street crime. They're familiar with that, and they don't understand — or are not equipped to handle — the putting together of a case sufficient to meet the standard that they have to meet in order to prosecute somebody.

There's a sign, I'm told, in some Arizona District Attorney's office that says, "Low-tech solutions to high-tech problems," meaning that they have few resources and

little sophistication, unfortunately, to deal with the high-tech problems that they are increasingly confronted with.

There may not be any easy solution to that, but I guess what I take away from the Stephen Jackson Games case, and from the cases that Lance was talking about and the cases that you read about, is that the day-to-day interface between this world that's growing increasingly and will have some real concerns about people committing conduct that requires that at least such conduct should be controlled by some type of criminal sanction if a true property interest is being violated — that if you don't have an existing day-to-day practice that is dealing with that, so that law enforcement is familiar with it — that you get the kind of aberrant case, here and there, that does the kinds of inappropriate things Lance was talking about, that you have in the Stephen Jackson Games case.

The materials that are provided here, for those of you who have them, have a listing of these various statutes. It's something that is not... each state now has computer fraud and abuse statutes of one sort or another. They differ from state to state, in addition to the federal statutes. There are state task forces; there are resources available for getting assistance with prosecuting these cases, but I think in the end it's a matter of the same type of thing you have when you have an embezzlement case or a business crime that law enforcement isn't going to pick up by themselves. It's more a matter of those people who are the victims of those crimes working more closely with law enforcement than usually happens, perhaps putting the case together and doing the investigation.

I also put some information in the materials from NIJ on what is required in order to gather evidence in a case of this type, putting that evidence and sort of presenting it all put together, so that something does happen if it should happen; because in the run-of-the-mill, more appropriate case it won't happen unless there's somebody who puts in that kind of input. So in addition I gave you a chart of the state statutes as they are in each jurisdiction, with indications of what kinds of categories they cover along with a description of the federal statutes and an excerpt from an NIJ publication on what types, from law enforcement's point of view — what they need in order to pursue these things.

The thing to be aware of in becoming, perhaps, open to gathering evidence and putting together a case is that there also are some very strict requirements in connection with the collection of this evidence, and in connection with law enforcement's activities in connection with collection of evidence.

Lance made reference to the Electronic Communications and Privacy Act. We're going to talk a little more about that in a little more detail this afternoon. Criminal law depends a great deal on the gathering of information and on the maintaining of the integrity of the information and on the observance of procedural rules. On the other hand, that doesn't tread on the privacy and the Fourth Amendment interests of citizens.

Probably the best example that we study in law school of how the courts have applied old principles of law to new technology was the case of *United States vs. Katz*, which is the case we studied in law school — a case that involved the federal agents putting a listening device on the outside of a glass-enclosed telephone booth. This was many years ago, and at that time the law relating to search and seizure was that, in order for there to be a search, such that the Fourth Amendment would apply at all, such that somebody could complain about evidence that had been gathered and seek to suppress it, you had to show that the government had intruded on property, literally on property, by trespassing in some way on property.

In *Katz*, the court said that rule just doesn't make any sense in the age of the telephone and wire communications. It's a resounding decision in favor of the application of the Fourth Amendment principles from the beginning of our Constitution to a new age. What they said is it's the legitimate expectation of citizens in privacy when they go into a phone booth. Even though it's a glass-enclosed phone booth, a public phone with everybody being able to see them, they have the same expectations of privacy in that setting as if the government had gone in and put the wire tap inside their own private home.

Building on the *Katz* case there was created the federal wire-tap statute, which created very stringent requirements for government or anyone to intercept, using an intercepting device of some kind, to intercept the contents of communications. It was originally oral and wire communications and then ECPA amended that wire-tap statute to include electronic communications. It's a very complicated statute; it always was, and ECPA didn't make it any simpler. It has lots of different provisions that you have to read in conjunction with each other, but basically what it says is that in order for government to intercept — well, nobody can intercept somebody's private wire communications, and the felony penalties are severe for private citizen as well as for the government.

Government agents, in order to intercept such communications, have to go through a number of steps. In order to get a wire-tap order out of a court, there are all kinds of limiting rules that apply. Unlike a normal search warrant, you have to show a judge you're going to make efforts to minimize what you listen to — only pertaining to what the crime you claim you have probable cause to investigate, that there were no other reasonable alternatives to gathering the information in that way.

A layer of complication that ECPA added onto this statute is that, as Lance mentioned before, it has two categories of electronic communications. They had wire communications and oral communications.

When they added electronic communications, the important distinction is between communications that are ongoing and communications that are in storage. What that means isn't as significant as it may sound when you hear what happened in the Stephen Jackson Games civil action that was brought.

Getting back to that case, because ECPA comes in to play, the Stephen Jackson Games bulletin board was located in Austin, Texas. Keep in mind that Riggs and [Nederdorf] were being prosecuted up in Illinois by federal agents. As part of the investigation, the federal agents obtained a warrant from a judge that authorized them to seize — and this is the wording of it — “computer hardware, computer software and documents relating to the use of the computer system,” and this is even Jackson Games' computer system and certain other documents relative to the computer programs and equipment which constitute evidence of federal crimes. This warrant is for the seizure of the above described computer and computer data and for the authorization to read the information stored and contained on the above described computer and computer data.

The reason that the federal agents sought to obtain a search warrant in the first place was because they had information that an employee of Stephen Jackson Games — which was not simply a bulletin board, it was also in the business of publishing books relating to certain kinds of computer games — that an employee of that company at his home had a private bulletin board which they thought was also engaging in activities related to the distribution of this 911 document and connected with the Legion of Doom people, whom they saw on the periphery of this action as well. In executing a search warrant there was no advance notice, as there usually is not, and agents appeared at Stephen Jackson Games and basically took the company's computer system, including

not only the computers and the disks on which documents and data were stored but also laser printers and modems and other devices that could have no conceivable— if you knew anything about the computer system — would have no conceivable relevance to the investigation.

Stephen Jackson Games was not a suspect in the case; he never was accused of a crime. It was a third party that had what law enforcement felt was evidence that was related to a crime. There is case law that goes back some years that search warrants can be executed not only on the premises of criminals for contraband but also [on the premises of] third parties, any of use are subject to having a search warrant executed if law enforcement can satisfy a judge that we are in possession, knowing or unknowingly, of evidence as well as contraband relating to a crime.

Stephen Jackson Games then sought to get this equipment back, explaining that [the company] needed it in order produce his business. On this equipment was a book that was in the process of being published and other important things, and on this equipment there was a bulletin board that was basically a customer service for the people who bought their publications. [There] was e-mail, including undelivered e-mail — more than 100 pieces of undelivered e-mail.

It took Stephen Jackson Games more than four months, despite the fact that they were working with a lawyer and had contacted their Congressman or politician to try and get the government to give the equipment that had been taken. It required them to lay off approximately half of their employees for an extended period of time, and they sustained, obviously, extended damages; so they brought a lawsuit, because, under ECPA and under a Privacy Protection Act, you can recover civil damages for violations of the statute by anyone including the government. If you can't prove actual damages there is a provision under the improper interception of in-transit communications of \$10,000 per incident, under Title 2, relating to stored communications. It's a lesser amount — \$1,000 per incident.

They were successful, by and large, in the district court, in having a judge award them damages for the seizure of this equipment without observing the ECPA requirements, because in order to intercept this kind of data as I said before, the wire-tap statute requires more than simply a warrant that says, "There is probable cause to believe there is some evidence there; we want to seize it!" It requires a showing that you're minimizing what you are taking, that you have no alternatives to taking it. There were very complicated procedures that were not observed there because law enforcement didn't concern themselves with that.

There is also an aspect of the decision which gets into more of the details of the statute that says under ECPA, stored communications as opposed to in-transit communications. Let me put the other way; we might think that in-transit communications would be e-mail that's undelivered. I'm sending you a piece of e-mail that's sitting on the Stephen Jackson Games computer and hasn't come through to me yet, I haven't picked it up yet. That would be considered in-transit communications for which there is greater protection, but a close reading of this statute according to this court at least — and there may be some basis for it — is that the way the statute is drafted with the combination of definitions and provisions, is that the only thing that qualifies as in-transit communications is when the data is actually moving over the lines and that whenever something is in temporary storage, including undelivered e-mail, it has a lesser status — still protected, but a lesser status of stored communications. So Stephen Jackson Games and the customers who joined this lawsuit recovered damages, but not quite the damages they were entitled to.

I mention that because it again reflects the fact that we have statutes out there that deal with these issues. There is a gap between the rapidly changing technology that's out there and the statutes and the knowledge of those who apply the statutes. The only way for these troubling events to be reduced, and not to increase, is for people who are in the world of the Internet and the world of these communications to, in a sense, educate law enforcement by seeking to have them observe what the requirements are and by educating legislatures to change the statute, if it needs to be changed, to be consistent with what the reality is.

I think that's basically what I was going to say today. We'll talk some more this afternoon about, if you're a systems operator, what you do in response to a warrant and what you do in response to a subpoena.

Wayne Martino: The next speaker that we have is Margie Seif. Margie is at AT&T On-line Network and they've just opened up a business network today. She's been doing this for a while. She was at Ziff Davis prior to that. Margie's just going to be giving you a general overview of things that she encounters on a day-to-day basis in the course of her representation.

Margaret Seif: I actually had asked to be moved from the 12 o'clock spot because I hate playing to the lunch-time crowd, but here I am playing to the intermission crowd. Because this is a long session I invite you to just raise your hand in the next 20 minutes while I'm talking. Feel free to ask me questions, because I may not be able to stick around for the whole Q&A session at 12:15.

I've been an in-house lawyer for an on-line service provider since 1993 and, as Wayne suggested, at the first we were content providers. Ziff Davis had its own on-line service called "ZIFNet," now called "ZDNet," on CompuServe, Prodigy and Apple's eWorld service. We were also developing an on-line platform to launch our own on-line service and Ziff Davis was sold in four different pieces in late 1994 and the platform software piece went to AT&T, and I went with that company. We turned into a hosting company that allowed publishers to put their own private branded services up and get their own subscribers; and if you wish you can subscribe right now to the *Washington Post's* service on our network or Ziff Davis has a service called ZD Interchange and a few other ones.

As of today, AT&T launches its first branded on-line service called the "AT&T Business Network" and I find myself now in the business of being counsel to an on-line service provider that's a content aggregator, not unlike AOL or CompuServe — an entity that gathers content from all kinds of providers and puts it together in an attractive package for users; so I feel I've seen it from all different angles. As I said, feel free to just raise your hand while I'm talking, and we can make this a more interactive little discussion.

In any event I have a worry list as in-house counsel for this kind of volatile industry. You would expect that the list changes from time to time; my list of worries last year was prioritized differently than the list this year, but the one message that I have for all of you is that the big on-line service providers like CompuServe, Prodigy, AOL, AT&T, Microsoft, face liability issues that I'll talk about.

You'll hear more from this panel, but really these problems are no longer just our problems. They are any content provider's problems who wants to put information up on a service, a commercial on-line service or on the Internet or on the Web, because increasingly, content providers — and I'll take my old alumni, Ziff Davis —

they're finding out that it's not enough to just take your print content and re-purpose it in an on-line medium. It doesn't really work terribly well. What content providers are finding that they have to do is make the content come alive on-line by adding interactive features like discussions. There might be chat. They find also that software files to accompany that content are very helpful to make it an interactive experience, so often they'll put up sound clips or video clips that go along with the print content that's up there, the editorial content. Increasingly, purveyors of content are finding that they need to subsidize their activities, because maintaining a Web site doesn't really pay for itself these days; so increasingly content providers are turning to advertising as a way to subsidize their on-line activities. Everybody is looking for that brass ring called "e-commerce" or transactions as another way to subsidize their on-line activities.

So when you put that whole package together you suddenly see that someone that might have thought of themselves as merely a content provider, with a Web site or a place on an on-line service, is starting to look a whole lot like an on-line provider themselves; as such, the problems I'll describe to you become the problems that are universal to anybody trying to do anything on-line.

My favorite saying is that Andy Warhol said that in the future everybody will be famous for 15 minutes, but I say that in the future everybody will be an on-line service provider because nobody, I think, in the next few years, will be without a Web Page, and that probably means every one of us human beings just sitting here, not to mention the companies that you all work for.

Just to give you a thumbnail sketch of some of the top three kinds of content worries that I have on a day-to-day basis, in no particular order of priority, would be: content that infringes copyrights or trademarks or trade secrets of a third party; potentially defamatory content, and obscene materials. I won't go into too much detail about the legal standards surrounding all of these various problems but I'll just give you a sense of what it's like in the trenches, every day, to deal with these kinds of issues and to try and do business in this environment.

With potentially infringing materials, material that's alleged to infringe a copyright or a trademark of third parties, I've found in the last few years that, really, the problem rarely will come up in the context of a content provider that is licensing its own content or, in the case of an on-line service provider, is the licensee of that content. To protect against it, I get a very full-blown indemnification from any content provider on our service, or from any publisher of a private branded service, and that indemnification covers every kind of problem that could arise with that content, including copyright infringements.

Where the problem has come up more frequently is in the member contributions that come onto the service, whether it's in the form of bulletin board postings or software files that are uploaded as shareware or as some other kind of distribution.

I find that we've had some interesting situations come up where a member will post a piece, maybe take a whole piece verbatim, like an article that they have seen, and they post it because it is germane to a discussion going on on the network. And then underneath that posting they will put copyright with the year and the name of the owner of that piece because to that member's mind, they are doing the right thing by citing the owner of work. The problem is that they never got permission from the owner of the copyright and so we have to tell them in a gentle way that they did the wrong thing and we take it down.

It also comes up in the context of shareware files or other kinds of software coming up on the service. People, I've found, that are very interested in creating shareware — and I don't want to malign the shareware community — but a technologically savvy group out there, they sometimes will take copyrighted elements that they've seen somewhere else and incorporate them into a novel kind of a program. It might be a screen saver, it might be game and they think it's their own work because they did create the program. They created the game and they created the software that makes the game run, only they never got permission from the owner of those characters that you've seen on TV shows or in the movies.

Again, we have to teach them; it's an educational process, but we have to teach them that they do have to go and get permission from Fox if they want to use the *Simpsons* or from Paramount if they want to use *Star Trek* characters, for example, and I don't think that Paramount will be too quick to give permission to Joe Smith in Padooka, Kentucky to create a screen-saver, because those kinds of large entities that hold copyrights and very valuable, recognizable characters want to exploit those characters themselves and don't really take it very well when others are creating products around their intellectual property.

I've also found that members have a very flexible understanding of what the term "fair use" means. Fair use, in a nutshell, means that there are certain circumstances where you may not have to get the copyright owner's permission before you copy or display the work. But there are standards surrounding what would be a fair use. They are very squishy, broadly defined, hard to define standards that a court would apply in a case brought by a copyright owner; so we urge people not to take what they consider to be a snippet of something because they think it's fair use and put it to some other use and post it on our network.

You may ask me why I care so much about what our members are doing. The answer is partly because members can get into trouble with copyright owners; and it's not in our interest to start a situation going that can escalate very quickly, but I care also because the copyright statute is a strict liability statute, meaning that, as the on-line service provider, we can be found liable for that infringement just as the member who posted the infringing work would be liable.

And, you may ask, "Who would the copyright owner feel that they could get more damages from, or do better in a case against? Joe Smith from Padooka, Kentucky, or AT&T?" I would guess AT&T looks like the deeper pocket most times, so I care very much. With the other on-line service providers like America Online and CompuServe and Delphi, we worked very hard to get the Clinton administration to pay attention to our concerns because they were promulgating what is now called "the White Paper" which suggested reforms to the copyright law in a digital age.

The Patents and Trademark commissioner unfortunately did not take the on-line service providers concerns very seriously and instead came down very hard in their report in favor of copyright owners' rights in a digital age. So again, the liability issue remains for us, and for anybody putting up a Web site where content in the form of editorial content or pictures or discussions are occurring.

The second sort of broad things I worry about is potentially defamatory statements made on the service. Again, I worry less about that from a purveyor of content like *The Wall Street Journal* who's going to be up on our AT&T Business Network because we have very broad indemnification from them and they carry what is called liable and slander insurance to cover this kind of problem. I worry about it much more in the context of bulletin boards maintained by us, where members can engage in

discussions and post whatever they want without that content being screened by us prior to posting.

You've heard something about the Stratton-Oakmont case against Prodigy. I won't go into the details here except to tell you that the court cited against Prodigy the fact that Prodigy has pre-screening software that they use before postings to bulletin boards are permitted up on the service. They have pre-screening software that looks for certain dirty words or racial epithets and the court found that that contributed to Prodigy looking like a publisher of the defamatory statements as opposed to a distributor of the defamatory statements.

You've heard that the case has been dropped, but this decision remains on the books, that Prodigy was a publisher of the statements, and so was subject to the same liability as if it had uttered those statements itself. We're looking for reversal of that decision and again, the various on-line service providers through the Interactive Services Association have filed an Amicus Brief saying very clearly that to leave this holding on the books would be incredibly problematic for our industry; but we're just waiting to hear and we don't have any resolution yet.

I look at that holding and I say to myself, "We have to start retraining our sysops, the people we use to monitor the boards, teach them a little bit about what defamatory content looks like. It's impossible, in fact, that anybody, any sysop or anybody else that's just monitoring the boards, can determine the truth or falsity of the statement in this kind of on-line context. It's just impossible.

We don't want to get into a situation where we look like we're censoring. It's not good for the on-line medium if the on-line service provider does not really permit free and open discourse of issues. If it looks like we clamp down every time there's something vaguely inflammatory up there, then we're not going to become a place that people want to visit and congregate and do their business and get to know each other. The defamatory content issue remains with me.

Every day we sort of worry a little bit more about some postings and we look at them, and the good news is that most of the postings never reach my desk. We have people who are very good at sort of gauging the level of discourse on a service, and we have member agreement and operating policies that set forth the terms under which subscribers should conform their behavior on the network, so there's a level of civility that we feel should be maintained. To the extent that postings seem to violate that standard of civility, we do take action, but it rarely comes from my office.

The third broad kinds of content problems that I've seen have to do with obscene content. Thankfully I don't see it on my service very much, but even though we are a proprietary platform — and I know that that's a dirty word these days — we are Internet-enabled. We provide the Netscape browser with every single subscription to the service, so anybody on our service can go out to the Net. They can go to the alt.sex news groups if they wish; they can download whatever they wish from that area of the Internet and they can store it in their e-mail, just like the subscribers did on America Online. Nobody is immune from this kind of material making its way onto their proprietary platform if they didn't license it.

With all the legislation that's suddenly emerged this year, we had it high on our radar screen that obscenity would be the next big issue, but I think that every single one of us in the on-line services industry was taken aback by the number of bills and the flurry of publicity that surrounded each one of the new legislative endeavors that was promulgated this last year, and we were very disheartened by the way the tenor of the

debate was going on in Washington. Those bills in their original form would have provided for criminal liability for anybody making obscene material available to a minor.

From all of our reads of those statutes, it meant that if I provide access to the Internet and somebody downloads a problematic file, and it's a resident on our e-mail system or somehow cached in a server, then the president of my division could go to jail for that. That seemed to me to be a very problematic result.

We worked hard as an industry to educate the legislators; and there was in fact a bill promulgated called the "Cox-Biden Amendment" which encouraged the development of blocking technologies rather than censorship, because you cannot censor the Internet. You can shut down a server in the United States with obscene material, but you cannot shut down a Finnish server. Instead, we should work to develop blocking technologies that parents could use to turn off content they found to be the wrong kind of content for their children. And we still remain in favor of that. The bill is in conference; we don't know what it will look like when it comes out, but I do maintain some hope for that. I think that the technology is coming along and, in fact, "NetNanny," I see, is here at an exhibition booth, so I may stop by and see what their blocking technology looks like.

That's my perspective from somebody who does this every day. If you ask me what my predictions for 1996 problematic areas will be, I'd put high up on the list taxation issues. States are looking for revenue. They need revenue, and they're looking at on-line service providers and Internet access providers to give them that revenue. Canada, for example, is trying to impose a tariff on any service that carries music, and the tariff is exorbitant. It's 25¢ a subscriber, no matter how much music. If you have one music file, ostensibly you could be subject to this tariff if you go into Canada — at 25¢ a user — or, if you're supported by advertising, I think it's something like 3.2% of all your gross revenues, so it's completely outrageous and we're working hard to get that squashed. It's called an experimental tariff, but I don't think we want too many experiments like that cropping up and flourishing because we'll be run out of business if we have to pay a tax collector and a tariff collector every time we do any kind of transaction on-line.

So taxation is a big one for next year, and I would believe also that privacy is going to come to the fore again. There was a problem last year, you might recall. America Online made its subscriber list available for rental, which is not an unusual thing to do. Many big companies do it. It's a good revenue generator. But the way that they advertised that the list was now available for renting gave users the impression that their individual data as to how they use that service would be subject to rental; meaning that if Joe Smith logs on to AOL and always goes first to sports and then goes to news, that kind of per-session information would be disseminated.

In fact, that's not the case, but it got Representative Markey in Washington very interested in privacy. He's no longer the head of the committee that was investigating this, but that lead to the industry saying, "No, we will never market per-session usage. We believe in respecting the privacy of our members." It was a misunderstanding all the way around, but I believe that privacy in some other forms is going to rear its head in 1996, and that'll keep us busy.

In a nutshell, every day is completely crazy. No day is like any other day in this job. There's always a new issue to keep you jumping and we're also trying to launch a product in the midst of all of this, so I hope that you'll go out to the booth and see the AT&T booth. We are making today available commercially launching the AT&T Business Network, which we think is just a terrific product, and I hope to see you all on-line.

Wayne Martino: Our next speaker is going to be Anne Branscomb. Anne Branscomb is at Harvard University and she is in the program on information services and resource policy. Anne has been involved in this area for a while and has written extensively, including law review articles in the *Georgetown Law Review* and *Yale Law Journal*. I'll turn it over to Anne.

Anne Branscomb: Thank you very much. Well, I think I'm asked to address only one legal issue today — or one that interacts perhaps with some others, and that is how we treat advertising and the First Amendment.

I guess we start out with "What is the First Amendment?" It really is an amendment to the U.S. Constitution, so the real question is how does this apply to a global network. It really has a very limited effect. It reads that Congress shall make no law. It certainly doesn't say that Parliament shall make no law or the Knesset or any other legislative body in the rest of the world that might have Internet messages there.

It speaks of abridging the Freedom of Speech and of the press, so I guess a threshold question is, does this cover the Internet or computer mediated communication at all? I think that there's no doubt that, under the U.S. interpretation, certainly on-line communication would be treated as speech. But the First Amendment, even if we look at just how it applies in the United States — it really is not a guarantee, it's a guarantee of the right to speak. It's not a guarantee of the right to be heard or a right to be viewed, so it's not really a right to be invasive, as far as individuals are concerned, into what they might consider their own private space. It does imply a right to distribute information, so there's no question that there is certainly a right to put advertising on the Internet.

Now, the First Amendment does run headlong, I think, into rights of privacy, and these are still in their primitive stages — just being developed. Although there are roots in the U.S. Constitution which go back historically, it's only in this century that we've expressed much interest in privacy. It's possibly because we only lived in small towns where people knew almost everything about us anyway, and we're only beginning to recognize the question of privacy and right not to have intrusive messages put into what we consider to be our private space. I think that people are claiming more autonomy over their own information, and as Margaret said there will be a considerable interest in the future in maintaining such privacy.

Now, how does this apply to advertising? Historically we've looked upon discussion as a marketplace of ideas or a market of information. This is certainly very consumer-oriented and I think we are in a mode in which we tend to favor consumer decision in terms of what is available. But historically, the First Amendment really goes back to a protection of the political life of the nation in terms of making public policy decisions and [discussions of] controversial questions of public interest. Commercial messages have only recently been held to come under First Amendment at all, though there, at least, a marketplace is something to which you invite people to come. It's not something that comes to you, and I think this is one way I look at the opportunities on the Web as offering a genuine marketplace to which people can come and find almost anything. Certainly, as this conference and World Trade Center activity suggests, advertising is coming to the Internet fast and furiously.

I think as we see this developing we're also seeing that we're coming into an environment in which there has been a great antipathy to advertising from the very beginning. Historically the Internet was governed by the acceptable use policies which

were for research purposes and education and not for exchange of commercial messages. They were in fact prohibited, but we all know that more than 70% of the sites now, or the domain names on the Internet, are of commercial interest. But a lot of the pioneers on the Internet don't like advertising anyway, and when they find it coming into the Internet they take the law into their own hands.

If you remember correctly a year or so ago, Kantor and Siegel, who were two lawyers in Phoenix, Arizona, spammed the UseNet groups. "Spamming" means throwing a piece of spam in front of a fan, which sends it in all directions. The people were very upset about this, because many people subscribe to different UseNet groups, and therefore they were receiving multiple copies of this advertising and they got very upset. There were flames; they stuffed the voicemail; they stuffed the e-mail of the Kantor and Siegel group.

One man designed software that would delete all the messages that came from that group, and eventually their server actually canceled their access to the Internet. Just earlier this year they went back and tried once again using a source that was not identified as Kantor and Siegel, so that it was somewhat deceptive. They in fact put messages into the equivalent of the 911 system, the management software for the Internet, saying that this was an okay message to be distributed, and it was actually distributed into the files which went into their distribution list for all of the publishers that they were trying to reach for their own dissemination of messages.

It actually was picked up so quickly by people who realized that this was Kantor and Siegel again, and the messages were being returned to their site, that their server canceled their service once again very quickly within 24 hours. Not very much of that got into the press. It's very interesting to see how much antipathy there has been on the question of advertising coming into that, particularly into e-mail and to conferencing groups.

Now, there is one question. I think one of the users had said it was sort of like opening your mailbox and finding hundreds of letters with postage due. There are some differences between e-mail and direct mail. There usually is a cost, there are limitations on the size of the e-mail box and so forth, so I think it's to some extent very similar to the situation that we found in the 1920s when radio first came on board and everybody was talking on all the airwaves, and there were so many conflicting messages going out over the radio that nobody could hear anybody, and the broadcasters were actually seeking some form of regulation.

So I guess we have to ask the question, "What really is acceptable behavior in terms of advertising on the Web and what are people likely to accept?" Of course advertising will be subject to laws governing advertising in other media which are largely regulated through the Federal Trade Commission. There some rule-making proceedings going through the Federal Trade Commission as to how the rules would apply specifically to the Internet and to commercial messages on-line.

Certainly, we won't permit fraud and any of the things that we have long since recognized as improper. There are some global implications, however, in terms of what may or may not be prohibited in other parts of the world, because once you put something on the Internet, it's certainly available in — I've forgotten how many countries it is at this point. It was well over 120 last time I looked. In France, for example, it is not permitted to place any comparative advertising, and that has become permitted in the last few years. We originally had such a rule but we changed that so that you can put comparative advertising. I think in France, also, ads have to be in French, which makes it a little bit difficult, although I understand the software is quite

capable of translating the languages. I read the other day that *Monopoly* is going on-line so you can play *Monopoly* in any one of seven or eight languages, and play interactively with people from different countries, so I guess the software can take care of some of this.

But what are advertisers actually doing on-line which is really very interesting? As Margie said, nobody's really making any money yet about trying to advertise on-line. Everybody is going to the Web, and it seems that what they're doing in order to not annoy the natives, so to speak, is offering free information, because information on the Internet has largely been considered to be free. I mean "free" in the sense that the end user is not aware of the costs that are associated with the exchange of the information on-line, because it's largely been in an academic environment. But it is very interesting to take a look at some of the different types of ads.

I'm sorry I didn't drag my computer along; I do have some pretty pictures of some of these but I suspect most of you have searched the Web enough to know them better than I do. There are such things as the "classic car site," which not only has classified advertising for all the classic cars all over the world but offers information about all the rallies you can go to and has little stories like "The Classic Car in Africa." They're beginning to offer a cluster of information — some of which is free — and expecting the cost actually to be — I mean, it's presumably supported by either classified ads or sites that are offering rallies and sponsoring them and so forth.

Godiva is actually offering free recipes on-line. My research assistant last year said he would download all the recipes but he didn't think he'd ever go buy any Godiva chocolate because it was too expensive; so if everybody behaves the way my research assistant does, Godiva won't make much money out of its Web page either.

Many of them are now turning to advertising on-line. I understand there's a good bit of advertising — it's fairly costly now — on the ESPN Home Page. *Hot Wired* obviously is collecting data on what sites one is interested in because when you sign in on *Hot Wired*, you have to give your e-mail address and have it verified and you have to have a password to get on it. I understand that *Time's Pathfinder* Page is going to something like that. I haven't looked at it recently so I'm not sure at what point they are.

But obviously it appears that the Internet is moving in the direction that television has gone — and radio in the past — of largely aggregating audience to sell to advertisers. So the question is: to what extent does this affect the purpose of the First Amendment in where you have a public forum and whether or not the purpose, as a free expression, will somehow be lost in this overwhelming control over the content by advertisers?

I think the question also we want to raise is: can we separate the advertising from the e-mail and the UseNet conferences in particularly. We do in the real world — not with the e-mail. We do with advertising. You don't find advertising inserted in the middle of a news message. It's certainly alongside, so that one can scan it, but it's not mixed up in the middle.

The postal system, of course, is not a very good model for e-mail on the Internet since we have largely turned it over to junk mail, and that's what we're seeking to avoid on electronic mail. I think we can say no to ads in the e-mail on the Internet as an invasion of privacy, if we assert that as a strong and legitimate interest. I think we can also say no to ads in such things as UseNet groups and ListServes, and so forth, as a private group space. I mean, we have private conferences, we have all sorts of legitimate reasons why we have to have private communication for groups who have legitimate

needs, professional uses, and so forth, in which they do not want advertising messages cluttering up that system.

But in order to do this I think we have to also raise the question of where there is a public forum that meets the needs and purposes of the First Amendment. I think we don't really have a problem with the First Amendment in terms of the two suggestions that I've made of restricting ads in e-mail and UseNet conferences so long as there is an alternative on the Web. The Web provides a perfect way of everybody getting their ads on the systems.

Now, where are the controls? One can say first that it can happen with just self-restraint, as many of the advertisers that are going on the Internet are currently exercising self-restraint and being very cautious in terms of what they're doing to try to find what's acceptable, what works and what's useful. But self-restraint is not a terribly strong sanction, and certainly when there are individuals involved, the weight of the power is on the side of the large corporations, with very little weight on the side of the individuals to force the change. I think that a law prohibiting ads and e-mail would probably pass constitutional muster; or requiring the mail to be identified in such a manner that it could be filtered, but I doubt seriously that Congress is going to take much of an interest in this area for a while, since there are other things commanding their attention.

Now, the second line of defense, I think, really is network managers, and I think network managers — I mean, a lot of people say the Internet is uncontrollable, that it's a worldwide, global network of networks and there's no administrative center, no brain, no central system. But there are network managers, and most of them do, in fact, make rules, so there is nothing to stop network managers from establishing protocols or standards of what they consider appropriate behavior as a general rule across the board. There would always be some that would not comply, no doubt, but it certainly is at that level that the control can exist.

I think more likely the direction that we will go is in terms of providing the kind of data management techniques that put identifiers into the messages so that you can screen out things that are ads. I think this works equally well with obscene messages and with anonymous messages if people don't want to receive anonymous messages, so I think we're beginning to see the move in the direction of providing much more autonomy at the level of the individual user and making the software itself do the job for which it is certainly well-suited, in terms of giving us an opportunity to screen out what we do not wish to have enter our own information space.

What are the advantages of something like the Web? It seems to me that it's a marvelous opportunity to rethink how we want to organize our commercial activities, our public forum, our political lives. It's much less intrusive than any other manner of distributing information. It certainly saves network resources if you don't send thousands of messages into e-mail but permit people to go to the sites in which they're interested at the time that they want the advertising.

It is really a true marketplace to which people go when they want something. I buy a car about once every four years, and I don't read in the newspaper every day ads for automobiles, or in the junk mail something luring me to buy a new car. So it's much more efficient in terms of economic use of resources to provide something like the Web. But I think if we don't act now to establish the protocols of how we choose to manage advertising on the Web, we will be overwhelmed by advertisers dominating it, and we may lose the public space to which we've historically gone when we were interested in discussing public issues. I think this is an important First Amendment

principle that we should apply, not only in our own country, but urge others to follow our lead.

Thank you.

Wayne Martino: Thank you, Anne. Our last speaker today is going to be Tom Hemnes. Tom is a partner at Foley, Hoag & Eliot. He is going to speak on copyright and trademark issues.

Tom Hemnes: Thank you, Wayne. I'm going to make this perhaps [short], because I think we were to leave a little time available for question-and-answer at the end, so I'll go through some of these issues very quickly for you and then perhaps you'll have some questions. I'm going to do it in the reverse order of what was in your materials. First I'll talk about trademark issues and then copyright issues.

The first trademark issue, and probably the most important one for people who are involved with anything having to do with the Internet, has to do with domain names. The Trademark Act, the Landham Act, defines a trademark as being any word, symbol or device that is used to characterize the goods or services of a particular individual and distinguish them from those of others. There is no doubt as a matter of trademark law at all that domain names, at least in many instances, particularly when they are used by commercial entities that are operating on the Internet, would constitute service marks for purposes of the Landham Act. This immediately gets into an issue.

As all of you, I'm sure, are aware, domain names are assigned by InterNIC, and in fact they are assigned by Network Solutions acting under contract with the government. They have been assigned traditionally on a first come, first served basis, and actually that worked pretty well for quite a while when non-commercial interests dominated the Internet. With the coming of commercial interests though, all sorts of commercial problems have developed and they are exactly the same sorts of problems that one would expect in any area of trademark law.

First come, first served gets very complicated when you're dealing with commercial names because what "first" means traditionally on the Internet means the first use on the Internet. What it means as a matter of trademark or servicemark law is the first use to distinguish the goods or services from goods or services of others, and what that implies is that you can be awarded a domain name for use on the Internet which is identically the same as, for example, famous trademarks.

I'll give some examples of these that have been awarded so far. There is mcdonalds.com, ford.com, coke.com, hertz.com, mtv.com, nasdaq.com, esquire.com, gmc.com, eton.com. Each of those domain names has been awarded to somebody other than McDonald's Corporation, Ford Corporation, Coca-Cola Company, MTV, Hertz, etc. As you might imagine, this is not something that warms the hearts of McDonald's, MTV, Ford, Hertz and so forth; and the question arises: who wins? Is it the person who went through the appropriate procedures and got the name that they sought to get from InterNIC? Or, on the other hand, is it the person like Ford who has been using the mark in commerce for say 80 to 100 years, or Coca-Cola an even longer period of time? This has produced litigation, as you might imagine, and the litigation has, from a trademark lawyer's standpoint, a completely predictable outcome. The outcome is that whoever has the right in the mark arising from long and continuous use in commerce will have a right that trumps the right that is granted by someone like the person who approves Internet domain names.

This is something that's been established in an even more telling setting in connection with corporate names. You can play the same sort of game with corporate names. I checked recently and found that you can register a company called "Mustang Inc." in the state of Delaware. You can form a corporation and call it Mustang Inc. But if you used that corporation and started selling automobiles under it, or automobile accessories or anything having to do with automobiles, the Ford Motor Company would surely be able to sue you and they would be successful. So this has created something of a problem for Network Solutions and for the awarding of domain names. It's not all as easy as simply looking at the directory of the names that exist now for the Internet and deciding which of them ought to be approved, whether the name that you're seeking approval for is on the list or not. It is not realistic for Network Solutions to conduct what we would call a "trademark search" for a variety of reasons. One is it costs a lot of money and they don't have the budget to do it.

The other is that you can never reach certainty with a trademark search. You can acquire rights in a trademark in this country — not in all countries but in this country — you can acquire rights in a trademark simply by use, and for that reason there is no directory anywhere that you can consult that will tell you all of the previously awarded or previously used trademarks. The result is that Network Solutions has really no way to tell if the domain name that you're seeking to use infringes somebody's trademark. The result of that is they have had to get a lot more legalistic, I'm afraid, than they have been in the past, and what they will ask you to do now if you apply for a domain name is both indemnify them against claims that might be made by third parties for infringement and also post a bond against any such claims. This is something that is done obviously to protect them against being the defendant as they have been in lawsuits where it's alleged that by awarding a name like hertz.com or nasdaq.com and so forth, they have permitted the infringement of a third parties registered trademark.

What does this imply to you if you are representing, or if you are in fact an Internet provider or user? Well it implies that you have to think of domain names in a new way. You have to think of them not just as telephone numbers in effect, but you have to think of them as trademarks. You have to treat them as trademarks and you have to approach them from a trademark standpoint. This implies that what you need to do is to do what Network Solutions can't do, and that is to ask yourself whether you have rights to use the mark before you apply to obtain the domain name.

It's not that difficult to do. You do what's called "a full search." Most people do it through a company called [Thomson & Thomson]. A limited variety of the search can be performed on-line over the Dialog network, and it will provide information about registered trademarks. It's pretty good, although for the reasons that I described before, it's not 100% certain.

After you have determined that you know that a domain name is available for you as a trademark, the next thing that you ought to do is really twofold. First, you should apply in the ordinary way for the domain name, and I would recommend doing that as soon as possible, as soon as you think you might want to use it.

Second, I would strongly recommend applying for registration of the name as a trademark. You can do that under United States law and also under the laws of most foreign jurisdictions on the basis of what's called "intent to use" in the U.S. You don't have to have actually used the mark before you do this. If you have an intent to use it, for example, on the Internet, you can apply for federal registration based on that intent.

Another thing you need to know about the way Network Solutions is approaching these issues is that if you have a federal registration of a mark you can use that to block an application for somebody else's domain name. If you don't, on the other hand, the other person may be able to go ahead and get the name before you. So doing both things — both applying for federal registration of the mark and applying for the domain name — in my judgment is something that is highly advisable for anyone who is going to be doing business on the Net.

Let me give you some examples. This is not news. I mean, a lot of people have been doing this, and the materials which we'll provide have examples of a number of applications for registration of domain names. Examples are "life.com" for providing access to an electronic bulletin board in the field of insurance and financial consulting; "brides.com" for a general interest magazine on lifestyle; "parade.com" general interest magazine services, health and lifestyle information. Those are examples. Undoubtedly you would be able to think of your own name or mark. That's the basic advice.

Now let me get into a little bit more esoteric questions, but I think that they are probably coming down the pike pretty quickly.

We were just discussing the question of Web sites and there is an emerging body of law that protects what's known as "trade dress." There was a fairly well known Supreme Court case decided in the last few years, called the "Two Pesos" case, that basically expanded the basis on which you can claim protection as a trademark for the way — it's called trade dress — the way you dress your product, the way you present it to the public. In Two Pesos, it was the design of a restaurant and you can imagine the trade dress being something like the distinctive layout. I think that perhaps McDonald's, perhaps, isn't as distinctive as it needs to be. Two Pesos was a kind of southern-style or Mexican restaurant.

Fuddrucker's is one that I think probably has a protectable distinctive trade dress. Trade dress can attach to virtually anything that is a non-utilitarian feature of a product, and when you think of Web sites you have to assume that a lot of the presentation of information about a particular company that's presented on the pages of a Web site is likely to be protected as trade dress, and in my judgment should therefore be considering whether they ought not to be registering those designs as trade dress. It's something that they can probably protect as a matter of federal law and it's something they would want to protect, I would think, to prevent others from passing off their goods or trying to associate themselves with the provider of the Web site. That's the first pushing the law a little bit beyond where it's been so far.

The second is a problem that I wanted to mention — and I think that it's a problem that may not confront you today, but is highly likely to confront you in the not too distant future — and that's what is known generally in trademark law as "trademark depletion." There are currently — the last number I saw, and I'm sure the number is bigger now — there were 82,000-and-change domain names. That was a couple of months ago. I think the number by now is probably getting up closer to 90,000 or 100,000 domain names. The number of words in the English language that people use from day to day in ordinary discourse is a few thousand. The number of words in a really good dictionary is about 300,000; and a lot of those are things, by the way, as you might imagine you aren't likely to want to use as a domain name.

If there are 100,000 of them used up already and if a lot of the other few hundred thousand English words are likely to be unsuitable for domain names, you immediately see the problem. We're running out of them. A domain name by its nature consists of a word or a series of letters followed by .com. It does not have to be an

English word, you can expand it a bit beyond the range of English words by having non-English series of letters, but nevertheless there will come a time, I think in the fairly near future, when finding an available domain name will prove to be difficult.

There is a special problem with this that makes domain names a bit different from trademarks. The principle in trademark law is that two people can have identically the same trademark as long as they are using the trademark with different goods or services. A classic example is Cadillac automobiles and Cadillac dog food. No one thinks that General Motors makes dog food and nobody thinks that whoever it is that makes the dog food makes automobiles; therefore, they can both name their product Cadillac without infringing the rights of the other. In the context of domain names there is a problem, though, which is that you can only have one instance of a domain name; you cannot have multiple instances.

So if you take the example Cadillac, let's suppose you wanted to have a domain name "cadillac.com." Either the General Motors company or the dog food company is going to get it but not both, and this means that the range of names that are available for use on the Net is necessarily going to be, in effect, smaller than it is for trademarks, which means the problem of finding an available name will be in many cases more acute.

To me this simply re-emphasizes the importance for people who are beginning to do commerce over the Net of worrying over this issue now and at least get them before they're gone — in terms of domain names — because the ones that will be available in the future are going to become more and more unusual, further removed from ordinary English and probably less desirable as trademarks because their association with your company, or with the product that you produce, will become more and more remote.

A couple of final comments on trademarks. One is that I mentioned [Thomson & Thomson]; I don't mean to be giving an ad to them, but they really dominate the field, though. They are beginning to provide, as part of what are called "full searches," searches of domain names, so you can find out if a domain name is available by calling [Thomson & Thomson] as well as under the traditional means.

Second, and this issue has to do with trademark infringement, there's a concept of "tarnishment" in trademark law that says that if someone else uses your mark in a way that may disparage your company or your product, you will have an action against them. Well, these principles apply to domain names as well as to other areas of commerce, and therefore, before you get too tricky with your trademarks you'll want to question whether you are possibly infringing the rights of someone else.

The best example I know of this was a domain name that you may have heard of which was "kaplan.sucks@review.com" which was taken out by Princeton Review, Inc. This is the review courses for MCAT and law boards and what not. This was objected to by Kaplan on the ground of disparagement, probably successfully. In any case in which you try to do — as Anne mentioned before — comparative advertising, not only compare your product with others but disparage the other's product, you're subject to that.

That's it on trademark. Let me say a few things about copyright. I guess what I'd say generally is that you ought to think of Internet as a copyright infringement machine. It's whole purpose is to take information, make copies of it and distribute them. When you get your materials you'll see that I've reproduced the very rudiments of copyright law, including what is protected as a copyrighted work and also the exclusive rights that copyright provides to the owner of the copyrighted work. I'll read down the list to you very quickly. Most people know this sort of thing intuitively.

Copyright protects literary works, musical works, dramatic works — that probably doesn't apply — pictorial, graphic and sculptural works, motion pictures and other audio-visual works, sound recordings and others, architectural works. Well, a lot of things are the things that are going out over the Net. Literary works, among other things, includes not only text but also computer software programs. Musical works, pictorial, graphic and sculptural works — those are all the things you're going to find either on the Net or on the WorldWide Web. They all under U.S. law and under the laws of virtually every other jurisdiction protected by copyright automatically without any need to put a notice on them, without any need to register the copyright. The protection arises by dint of their creation.

What are the exclusive rights that the owner of copyright has in these things? Well, they are the rights that you might imagine. The first is the right to reproduce the copyrighted work in copies or phono records. Second, to prepare derivative works may or may not apply, the first certainly does. Third, the right to distribute copies of the copyrighted work to the public by sale or other transfer of ownership or by rental, lease or lending. Fourth, the right to display the work publicly. Fifth, the right to perform the work. Sixth, the right to perform the work publicly.

Well, when you think of what goes on over the Internet, virtually everything involves taking, at a minimum, a literary work — something that's written out in some language — and making it available for distribution in copies to anybody who logs onto the Net.

There may be some variations in the way this works out. If you take an e-mail document and you attach something to it, you attach another document to e-mail and then you send it to someone, there is no doubt in my judgment whatsoever that you have made a copy of the document attached and you have distributed it. You may not have distributed it publicly as long as you send it to only one person. If you send it to enough people, though, that would be considered a public distribution. That would be considered, I think, beyond any question an infringement of the exclusive right of the owner of copyright — the document you attached to your e-mail.

Similarly, if you take a photograph — there was the famous *Playboy* case involving photographs out of *Playboy* — if you take a photograph which is a pictorial work protected by copyright and you distribute it over the Net, you will be infringing the copyright held by the author or assignee of the author of that copyrighted work.

The issue gets a little bit more tricky if you deal with issues like bulletin boards. If you don't yourself distribute something over a bulletin board but simply make it available for others to download, then there's an argument at least that you have not yourself distributed the work publicly. On the other hand, there is very likely to be a copy of the work created at least in a server to make it available for distribution over the Net and that copy of the work, unless it is authorized by the owner, would be enough in most cases to establish a case for copyright infringement. Furthermore, the fact that you posted on a bulletin board to make it available for distribution would, I think, lead to a strong argument for what's called contributory infringement even if you aren't liable for direct infringement.

The moral of these comments is that the copyright law is something that you need to have on your mind when you are working in the Internet environment all the time and the default setting for people who are involved in Internet activity should be — don't do it.

I'm sorry to say that this is as clear as that, but the copyright law is rather vivid on these points. If you didn't create it yourself, if your company didn't create it, if it

came from somewhere else, the odds are that what you want to do with it over the Net at least arguably creates liability under the copyright act. This means that you have to find where you can appropriate licensing authorities to do what you want to do. In many cases people will be happy to give you a license. In some cases, on the other hand, they may not and they could object.

As an example, it's something that we had to worry about in connection with the presentation today because the materials we are providing are, I believe, going to be provided at a Web site. What guys like me usually do with presentations like this is run off and xerox a bunch of *Law Review* articles and whatnot and make them available for the people who attend the seminar. Usually you can; it may be a fair use, it may be a violation. Usually the assumption is that you can get away with that with a limited number of people at a law seminar.

But when you think about posting one of these things at a Web site, you really are multiplying the problem by many thousandfold and therefore you're multiplying the risk that someone might object by many thousandfold and it's something to which you need to give care and attention.

I'll quickly mention two more things. One, vicarious liability for the person who provides the network service, and by that I mean a server. This is an area of the law that I think will need to be developed. I think in many cases it may depend on the extent to which the person acts like a publisher on the one hand, or like a common carrier on the other hand. A publisher traditionally is liable for the content of the publication. If you publish a book and the book infringes somebody's copyright, even if you didn't write the book, even if you didn't know that it was an infringement, you can be liable. On the other hand, if someone recites a copyrighted work over the telephone, the telephone company is not liable for an infringement of the work, and I think that will be the battleground.

There's more, but I'll stop there. Maybe you have questions. Thank you.

Wayne Martino: We've run over a little bit. I think people are going to stay around for a question and answer period. Does anybody have any questions?

W: I'm curious what the panelists think about any kind of lack of understanding of the technology by legislators [inaudible]. How does that impact what's going on right now?

Wayne Martino: The question is, what is the lack of understanding of technology and the impact of that on legislators and lawyers? I think it's absolutely incredible. I think most lawyers are not computer literate, judges are not computer literate and they don't understand the context of the technology.

Lance Rose: It's a changing thing. I've been doing computer law for 15 years and judges have always had to have that stuff explained to them. Did Ken mention the Stephen Jackson Games case? Did he mention that the trial counsel actually brought a computer in and showed the judge what a bulletin board looks like? He didn't mention that part?

Wayne Martino: I don't know if he mentioned that.

Lance Rose: Because that's kind of what you need. I was talking with somebody about this the other day. In fact this law firm I just joined, this big law firm in Phoenix, it's like, "how are we going to get the other lawyers there Net-savvy? How are we going to tell

them how it works?" I said we've got to bring a laptop in and show these guys. There's a distance.

It's like asking a judge to adjudicate things that are going on in Mars. Legislators love it. You know the Exon Amendment? Exon has been going around with his little blue book, apparently full of pictures trying to get this thing — which was passed — trying to get as much of it actually into the reconciled bill as possible, and he's been telling the other Senators, "click, click, click, and there it is." Pornography, bestiality, bondage, anything you want. Of course, these guys are all thinking about their political hides, but there's this new layer of mystification on top of it which makes the politicians not only afraid for their hides, but not quite sure what's going to bite them. So it makes it really a very kind of crazy area of regulation right now.

W: I have a question for the last presenter that you had — kind of a two-part question. In terms of say a company that has a logo, for example, that they have — I don't know if the correct word is trademark or copyrighted — with the degree with which it could go from the Internet and Web pages now, I know there is some responsibility on the part of the owner of that image to police its usage in the world at large. So how does that apply to people using it, for example now, on the WorldWide Web? What is the image owner's responsibility to actively go out and search for that being used on the Web?

And then, the second part of the question would be: if you have something like an Internet service provider that has discussion groups, and they set up a discussion group that pertains to that particular product, [inaudible] what is the degree of their right to, sort of, sell their service using this feature as part of what they advertise that they offer? And do they have a responsibility to clear that with the company whose service [inaudible]?

Tom Hemnes: Your first question, I think, is whether you have a responsibility to police the use of the logo and in particular go out and actively search out people who may be infringing. The usual rule is that the owner of a trademark does not have a responsibility to go out and ferret out every infringement. On the other hand, if you become aware of infringements and don't do anything about them, there are a couple of problems that you can encounter. One problem is that the people that you become aware of may acquire a defense either of acquiescence saying that you knew about it and you delayed in asserting rights and in reliance on that they continued to use the mark.

The second problem is that if you in fact don't police the mark effectively, although there isn't an obligation to, but if you don't police it, then the mark comes to be widely known as denoting a particular type of service or particular type of good as opposed to your good or service. You can encounter a problem of "genericness." An example of that is that there are famous companies — Coca-Cola actually has what they call "the Coke police" who go around and march up to a counter and say, "I'd like to have one of them Cokes," and if the restaurant is serving Pepsi, they'll get sued and the reason is they don't want Coke to become a generic term for a cola soft drink. So I think that was your first question.

Your second question has to do with a couple of related issues. Let's assume, hypothetically, that you had a discussion group pertaining to some trademark product. There would be, at least in this country, a perfect right to refer to the product using the trademarked name which would be considered a fair use of the trademark. I mean, what else are you going to call it if you don't call it a Corvette or whatever? Second, you

asked the extent to which you can use the other person's trademark to sell your own product. Is that right?

W: If there's an on-line service that features these kinds of discussion groups and they use it to attract [inaudible].

Tom Hemnes: I would think that if you were *Consumer Reports* and you said, "We're going to have an on-line service to talk about automobiles and the ones we're going to talk about this month are Chevys, Fords and Chryslers," I think that would be fine. On the other hand, if you were doing it in a way that conveyed a sense that you were sponsored, or affiliated with, or associated with the proprietor of the trademark, you probably would have crossed the line into an infringement. Is that helpful?

W: Thank you.

Wayne Martino: Next question.

M: If I get a press kit including promotional material from a commercial operator and it includes logos for a nationally manufactured product which they have the right to distribute as a retail outlet of that, say, Amana or something as an example, and they distribute this in a press kit and without their knowledge I put that on a Web site, what are the — if any — legal implications of that?

Kenneth Rosenthal: What are you doing at the Web site? What's the purpose of the use?

M: Let's just say that the Web site was going to put a whole bunch of commercial information available so the users can come look at it at no charge to either the displayer or the user looking at it.

Kenneth Rosenthal: Hard case. This is just an [inaudible], I mean, you're just being a nice...

M: This is true. It actually happened.

Kenneth Rosenthal: It's a public service that's being provided in effect?

M: Well it is, except that the intent for this site is to sell advertising on it once they get in the pits and become a demand [inaudible].

Kenneth Rosenthal: If they're selling advertising on it then I think that the people whose marks appear would have a claim. On the other hand if it's simply informational I would think that they probably would be able to get away with it. Does that sound right?

Lance Rose: Well, legally. But if it's a real situation, first of all you're republishing other people's published materials. That's the first [inaudible] you've got to be concerned about, not the logos included.

M: Even the press kit?

Lance Rose: The first thing you're doing is reproducing something you got from somebody else. You're republishing, and you've got to think about the copyrights and whatever rights they have before you about the logos on their stuff. First, that's number one.

We're really into motivations. We're really into who is bothered about this. Somebody who is selling a product whose mark is being re-propagated in another form that they didn't have to pay for, and let's assume you're not running a porno site, is going to love it. It's going to be very, very unlikely — not impossible, but you're looking at low level risk. I'm not giving you specific legal advice, but you are looking at a low level of risk for people whose brand names you are propagating in a way that they don't have to pay for it. They're getting extra mileage for their buck.

The people that might be bothered are the people whose stuff you're republishing without their permission. They're not controlling the publishing medium anymore. There's another practical thing. Anybody comes to you about it, this is very standard infringement stuff. The fastest way to knock the legs out of an infringement claim is to say, "Okay, I'll stop." The primary remedy in an infringement claim is an injunction. "Okay, I'll stop." What are they going to sue you for, money? What money are they going to show you made out of that?

One mark out of, say, thousands displayed and you made a few thousand bucks that month, what are they suing for, a dollar? They're suing you for a dollar, maybe. So these are the practicalities if you're in a real situation. These are the practicalities that you look at on top of the legal analysis.

M: So your advice would be to have some kind of release even [inaudible].

Lance Rose: My advice? I'd have to find out a lot more about what you're doing.

M: I'm not doing it but I'm aware of a publisher doing it. They have asked if they should get permission from these people to do this.

Lance Rose: The logo people? If it was me, I'm not telling anybody else to do this, I wouldn't be that concerned about the logo people if I was running a fairly reputable-looking Web site. It doesn't mean I wouldn't look in to the property issues, but my first level of inquiry would be, what are these materials that I'm receiving in my hands that I'm reproducing? That's the publications that you're most directly reproducing, first level of contact.

M: Second question. If you spent thousands of dollars scanning this information in and created a site that had 4,000 pages on it of all these materials that you had been provided, and a competitor of yours downloaded that and put up a competitive site using that material, what rights do you have if they haven't altered it, and then what rights to you have if they have altered it, put their own borders around the pictures and so forth?

Tom Hemnes: If you have compiled a — and let's suppose hypothetically that one way or the other you had a right to do it — compiled thousands of pages of things that are available in other places but are never collected in one place, that compilation is a separate, copyrightable work in which you could claim ownership. If somebody else

copies the whole compilation, they would be infringing your copyright in the compilation. I think that's the short answer.

W: [inaudible]

Wayne Martino: The question is: What are the international aspects of trademark and copyright infringement?

Lance Rose: First of all, what's the likelihood that if you're infringing someone's rights in another country they're going to haul you into court in that country? And that depends on what type of organization you're with.

The fact is that trademark rights are national. They're even, within this country, state by state in a sense, but they're national, so there actually are dozens or hundreds — for certain brand names — of perfectly legal claimants to a given trademark on-line. This is apart from the domain name issue, whether you're using a domain name in some other way. Bosco - I don't know what the rights are to Bosco around the world. Maybe they're all owned by one company, maybe there are a lot of companies that own them. Maybe it's legal here but not legal in Spain, hypothetically. Maybe it's legal here and not legal in France or Lithuania or Germany or something, and this is absolutely not touched yet.

This is something that, from the lawyers I know, nobody has worked out. This is craziness. We have a globe-spanning Internet and we have a bunch of national-based trademark right regimes and these have not been reconciled in any fashion, and even the theories about how to reconcile them are just starting to be thought about, at least in my experience.

Tom Hemnes: I might make a few additional comments. The domain names that are available in Europe and in the Far East are awarded by different entities than in the U.S. If you want them, I have the e-mail addresses if you like. You can get a domain name there. So, it would be — if you are serious about it — it would be very advisable to seek to acquire the domain name under the aegis of those organizations as well as under the Network Solutions organization in the U.S.

The second is — and this is where I'm not sure what the answer is — but in principle marks that you can register in the U.S. are frequently registrable abroad as was indicated on a country by country basis. There are some exceptions. There are some international regimes to which the U.S., unfortunately, is not a party that would make it a little bit easier to do it; but basically, as a U.S. resident, you're going to have to do it country by country.

In most countries you can do it, though, in anticipation of use, so if you have a desirable domain name, you can try to register it abroad. There will be some issues. There are description problems in other countries that you frequently don't have here. Some countries make it more difficult to register service marks than in the U.S., but in principle you can register them abroad, I believe.

M: In the discussion in the Internet industry upstairs this morning as well as some of the other discussions I have heard, there is an argument being proposed that the Internet is a public medium and people knowingly put this information that they have copyrighted onto this media and therefore you should essentially transfer the copyright ...[inaudible].

Tom Hemnes: Let's take the case where you are clearly the owner of the copyright in say a literary work, an image text or a computer software program that you post on the Net. I think that if somebody took it down off a bulletin board for example, they would have a pretty strong argument that in posting it there you had, unless you indicated to the contrary, you had by implication granted a non-exclusive license to them to download it; and that may be what they were talking about. I would consider that to be a fairly compelling argument.

Wayne Martino: I think you'll find out in a second, because Lance is biting his lip here, that some people may have a different view on that.

Tom Hemnes: What I was going to say, though, is that you... I think that maybe this is what Lance is about to say — it seems to me that you can negate that argument by giving notices of what your claims are when you post it on the Net. In other words, if you say we are not by, you know, maybe you make a demonstration model available, that you are not by doing that, by implication, granting a license for any other use. I think that might help.

INTERNET LEGAL LIABILITY OF SYSTEM OPERATORS

MODERATOR

Wayne Martino, Esq.
Brenner, Saltzman & Wallman

SPEAKERS

Lance Rose, Esq.
Partner, Lewis & Roca
Ken Rosenthal, Esq.
Brenner, Saltzman & Wallman

Wayne Martino: I think we are ready to start. This is [a session about] the liability of systems operators. Lance Rose, who will be speaking first, is a partner at Lewis & Roca in Phoenix. He co-chairs their intellectual property department, and Lance has been writing about this area for a long time, including writing one of the first books on this called *SysLaw*. He also has a book called *NetLaw*. Is that a successor to *SysLaw*?

Lance Rose: Yes.

Wayne Martino: I highly recommend both of them. The second speaker will be Ken Rosenthal from Brenner, Saltzman & Wallman in New Haven. He will be speaking about criminal issues, and specifically about how to respond to subpoenas. At this point I'm going to turn it over to Lance Rose.

Lance Rose: Hi. This session, I believe, is called "Liability of System Operators," so that is what I would like to address. It kind of leads to the question, "What is a system operator?" A system operator is [also called] a "sysop," and you may hear me use that term a fair amount. I think that's kind of how "Webcentric" and Web-oriented things have become, where the concept of gets lost in the wash sometimes.

Now, what is a sysop? What is a system operator? Is a system operator someone who runs an advertising site or a billboard on the Web? I don't really think so; that's somebody running some advertising. Is it a Web publisher on today's Web? Is a sysop somebody who is running a "Cool Site of the Day," or something chock full of interesting information for people to point at and click around? Again, probably not, not really. Is a sysop one of the legions of upcoming people who offer on-line shopping services? We're all waiting to become law firms of on-line shopping services as soon as those secure digital payments are under control. I don't really think a sysop is one of those people, either. They may be on-line store proprietors, but not a system operator in the way that term has been used.

A sysop is probably, more properly, someone who offers group interactive services. There is actually quite a lot of tradition, going back to the 70's — at least the 70's, maybe the 60's, but probably the 70's — of people running computerized communication systems where they moderate discussions or in some sense sustain a support discussion among groups of people. They're sometimes referred to as "threaded discussions," or "conferencing," and I think we will see sysops coming to the Web more rapidly if the deal that was announced between Netscape and a company called Calabria comes to fruition. Calabria, as I saw in news reports, was referred to as "the creator of software that allows threaded discussions and conferencing," the two things conspicuously absent from Netscape up until now.

There are bulletin boards. There were bulletin boards since the mid-70's, since Ward Christensen's first bulletin board, and those have always been group discussion areas.

Large on-line servers have been around for a long time, with CompuServe, Prodigy, The Source before that, and America Online and others coming up.

NewsNet is the place for newsgroups, and those are all discussions with bunches of people yakking about stuff.

There are mailing lists. How many people here are on mailing lists, Internet mailing lists? Pretty good, about half. Mailing lists are pretty cool. It's a conference in your mail box, and those, of course, are group discussions once more, kind of do-it-yourself, roll-your-own-group discussions that are often impromptu and also often long-lasting, going over months or years.

There are real-time "Chat" type areas — I guess it's still called chat, I don't know what else it might be called. There are sometimes people who monitor those areas, and they've got to be pretty light on their feet to get anything accomplished other than shutting people out when they don't like the way they're behaving.

There is a lot of interactive stuff out there. You're not going to see a lot of it on the Web, but there is a lot and the Web is moving in that direction.

Oh, another one I forgot to mention was MUDs and MOOs. Here's a good one: how many people here have been on a MUD or a MOO? That's pretty cool — more than zero. Obviously a lot of people do go to them, but most of them are kind of sitting at the terminal in the college dorm right now instead of attending a conference like this. For those of you who aren't familiar with MUDs and MOOs, those are virtual reality environments, group-interactive virtual reality environments which right now are mostly text-supported. They're mostly text descriptions of what people look like and what they do, what they're doing, what kind of places you're in and where you're going. It's kind of multi-person interactive "Zork," although it's heading in the direction of graphical virtual reality in the not too distant future with things like VRML — Virtual Reality Modeling Language — and applications like Worlds, Inc., which I believe has one in *Virtual Vegas*. There's a lot of virtualized visual environments that are coming up, all very highly interactive.

And there's also this real-time chat function; you might consider a chat monitor person as a sysop, but usually those people aren't really the sysops.

Usually the sysops, the system operators, are the people who manage the slow-motion discussions that happen in conferencing areas. Somebody posts a thought — "posting" is the typical verb used — somebody uploads or posts the message, says something, and somebody else responds to it in an active bulletin board-type setting. [The response] could be within a few minutes; in a relatively inactive one it could be half a day or a day later. Everybody who logs into this area will see that stuff, and it doesn't take long for those of us — and I imagine it's most of us at this point — who would see such discussions to understand them as discussions and to understand it as a bunch of people interacting.

I'm sure you're all aware of the standard ratio of people who verbally interact to the ones who are just standing around, logging on and looking, and who are known as "lurkers." There's usually about an 8-to-1 to 10-to-1 lurker to active participant ratio, so every time it looks like you've got 30 people having a discussion it's more like 250 or 300 people being directly aware of that discussion.

You know, I have talked about these big legal issues so much over the years, what I want to do now is kind of give a framework; then we'll have a question and answer session after I and Ken finish speaking, and if you have more particular questions we can get into it then.

The big issues for system operator liability could be put a number of different ways, so I'm going to just put it one way and hope it will make sense. One issue for somebody who runs an on-line system where people are interacting is whether they have to monitor everything on

the system. Do they have to look at everything going through the system? Is there some kind of legal responsibility for that? If not everything, if you don't have to monitor everything, do you have to monitor anything? If you have to monitor anything, what is it that you have to monitor? These questions are all out there right now, and aside from what messages and types of files you might have to monitor, what are you looking for? Are you looking for things that are illegal? Are you looking just for copyright infringements? Are you looking for defamation? Are you looking for people illegally exporting encryption software? Are you looking for people posting credit card numbers? Are you looking for images from magazines? Are you looking for pornography, obscenity? What are you looking for? And, of course, aside from what they're looking for, what system operators really care about is none of that, of course. What system operators care about is the bozo who blunders into an on-line conference and screws it up and drives everybody out. If it's a paying board, the person who does that makes them lose business.

Those are the ones they're really on the lookout for, and that's what they're monitoring for. Not that they don't care that people get ripped off, but that's not what's most germane to their business. What's most germane to their business is having a place where people are interacting in a way that they feel promotes what they're trying to do, either commercially or noncommercially.

So we have this interesting thing where, of course, most system operators are looking but they're really not trying to protect the rest of the world from itself. They're trying to make their own business run smoothly. It's like if we had a monitor here in this conference room. The monitor isn't really looking to see if somebody's infringing copyrights; they're looking to see if anybody is getting up and attacking the other people in the room, because it makes it unpleasant and everybody's going to leave and they want to keep the session going. That's what the system operator really has their eye on, and the legal stuff is kind of an impingement from the outside.

Aside from monitoring, the other big question, of course, is that once the system operator knows there's something on the system — hey, there's a copyright infringement, and they hear this from a reliable person — what are they supposed to do about it?

“Okay, thanks, you told me. I'm a distributor, I don't care.”

Or, “Oh, a copyright infringement? Maybe I ought to look at that.”

Or, “A copyright infringement? Maybe I ought to take it off the system, and then if anybody complains about having taken it off the system maybe I'll put it back on again.”

There's a whole question about what the proper conduct is. There's also a whole question about what knowledge is. If some “boy who cried wolf” person tells you that there's illegal stuff — what if somebody says, “your bulletin board, your conferencing area is full of copyright infringements, check it out.” As a system operator, have you now been placed under a duty to check it out because somebody says it's full of copyright infringements? I would be tempted to wonder how credible that kind of comment is. I might e-mail back to the person, “please be a little more specific. Which files? Where? And tell me why they're infringements.” But these are still questions that are being asked.

There have been a few cases and they give, maybe, beginnings of guidance. One case is [Cubby] vs. CompuServe. It happened in the beginning of this decade, in the Federal Court in the Southern District of New York. CompuServe was carrying an electronic newsletter called *Rumorville* — no, I don't know if CompuServe was carrying *Rumorville* — but there was an electronic newsletter called *Rumorville*, and CompuServe was carrying another electronic newsletter which I believe was called *Scuttlebutt*. *Scuttlebutt* was the new kid on the block — wait, let me back up off of that. These aspects of the facts are not that important, but I don't want to get it wrong.

There were two electronic “rumor” newsletters, and one of them said bad things about the other just like gossip sheets will do. They say bad things about other people; one of them said bad things about the other. The one that had the bad things said about it went after the electronic newsletter where the bad things were said and also after CompuServe as the carrier of the electronic newsletter. They said, “you carried it, you’re responsible for it.”

CompuServe said, “we didn’t know about this stuff. There’s a lot of stuff going through our system. We have a person managing that area of CompuServe. That person managing that area of CompuServe has a contract with these people that do the electronic newsletter. If you’re going to bother anybody, go bother them. We don’t have anything to do with it.”

They actually made a motion to the judge, essentially saying, “we had nothing to do with this. Let us out of this case. We did not put the materials in this newsletter together; we don’t know if it’s a defamation or not, and we don’t care, we’re just the distributor.” The judge went with it. He said, “that’s fine, you’re out.”

CompuServe distributes a lot of information, and the judge felt this is an important function, this is a First Amendment speech function, this is part of the freedom of the press in this country and CompuServe is kind of an essential channel for freedom of the press. Freedom of the press is not real useful if the words could be stopped on the way out of your mouth, if you could say anything you want but they got blocked before they got to the speaker. CompuServe is one of these conduits through which words get to the speaker. The court made analogies to bookstores and to magazine distributors as similarly protected.

If they don’t know about the stuff they’re distributing then they can’t be bothered by a lot of legal burdens, because if you make CompuServe, for instance, start to monitor for all the defamatory information on the system, that’s a hardship. There’s a whole lot of non-defamatory information. In fact, that’s quite the bulk of it; that might be 99.9% of it, and that’s perfectly legal information.

[In the Stratton Oakmont vs. Prodigy case], the fact that this anonymous person who said these bad things about Stratton Oakmont was using an account that had belonged to a Prodigy employee who left the company, where the account was never retired and somebody found a way to use that account without being identified — it kind of looked like Prodigy did something wrong there. Why were these accounts left hanging so that people could jump into [them] and anonymously leave bad messages? It doesn’t really stand up under a close analysis that Prodigy should get into any trouble particularly for that, but it just made them look sloppy and more open to having some kind of responsibility pinned on them.

Prodigy also mentioned, when this motion on this decision came up, that it had stopped monitoring a year or two before the messages in question occurred; but the judge seemed to feel that didn’t make a difference. The judge seemed to feel that whether or not Prodigy monitored, what was more important was that they were telling the public that this was a safe place, and they had taken some obligation to keep it safe and see that all the messages were safe. So we had this decision and it drove everybody in the on-line services industry kind of crazy. And then a funny thing happened.

Prodigy fired its lawyers and hired another lawyer, somebody with a reputation for First Amendment work — entertainment lawyers, but with a reputation for some First Amendment savvy. The first thing they did was move to re-argue that same motion, saying that was just a preliminary motion. The judge said that Prodigy is a publisher and not a distributor, so they’re not just going to slip out of the case the way CompuServe did. Prodigy said, “we’re going to reargue that motion. We’re going to try to convince you, judge, that we really are a distributor and [that you should] just let us out of this case now.” It’s not very usual, but it happens every now and then in litigation.

When this opportunity came up, a lot of industry groups now saw a chance to jump in and try to reverse this shocking result which the judge had come to, and some pretty compelling briefs were filed on behalf of chunks of large companies. This was just a lot of action. And then a very funny thing happened, I think last week. Stratton Oakmont, the plaintiff, gave up on the motion to re-argue.

They already had the motion in their favor saying that Prodigy was a publisher, and when they gave up arguing against a re-argument, and in a sense they handed the motion to Prodigy. It was kind of reversing the result, [with a new result] that Prodigy would be considered a distributor again. There was also a public statement from Prodigy saying they were sorry if Stratton Oakmont got hurt from the bad things that were said about it on Prodigy. Stratton Oakmont lawyers said, "We got what we wanted; Prodigy admitted responsibility." Prodigy's lawyers said, "We did no such thing, we just said we were sorry if they got hurt." That's nice room for posturing there.

Supposedly, we now have this decision on the books that says that Prodigy was a publisher. Apparently, now Stratton Oakmont is going to work with Prodigy to try to get the judge to vacate that earlier ruling, so it's not in any sense out there as law for other companies to rely on in going after on-line services.

How did this come about? How did this interesting thing happen? This is just something that comes out of the particulars of the case. Stratton Oakmont, this company that had the bad things said about it, has been under a cloud with the Securities and Exchange Commission. The question really wasn't, "Is this a suspicious outfit?" The question was, "Which things that are being said about them are true?" When Prodigy hired its new lawyer they made it clear that what they were going to do was vigorously pursue the truth as a defense to libel. There is really no way of knowing if the statements that Stratton Oakmont were suing about were true or not, unless you do discovery and find out everything about Stratton Oakmont.

As a company under a cloud with the SEC and the securities regulators, what they were facing was the prospect of very extensive discovery and the possibility of going into the public record with everything they'd been doing for the past few years, and it looks like this was the basis on which this whole thing has kind of unraveled. That's kind of an example how off the issue these things can end up being decided on. Those are kind of the two cases that have come closest to saying anything about this issue. I'll mention briefly some other things.

There have been some cases in the copyright area that are related to this. One was called *Playboy vs. [Freina]*, down in Georgia. There was a bulletin board there that had pictures from Playboy going through the system. The pictures from Playboy even had ads for the bulletin board imprinted on the picture — if you looked at a picture on your viewer, it would have the name of the bulletin board, Text Warehouse, in the bottom of the picture. Nonetheless, the bulletin board operator said he didn't know these pictures were on the system.

Playboy moved for summary judgment on the issue of copyright infringement. They said, "Look judge, all these pictures taken from our magazine are there, they're on the system, just give us summary judgment. It's absolute liability for distributors." The person who ran the system said, "I didn't know about it." Even though it was kind of clear he did, he said, "I didn't know about it." When the judge was faced with the summary judgment motion, when the guy says, "I don't know about it," he actually has to give some credit to that, even if it seems on the facts that this is kind of a ridiculous statement. This led the judge to say something that, again, drove the on-line system lawyers kind of crazy. He said, "it's irrelevant whether the system operator knows or doesn't know about the copyright infringement on the system. They're going to be liable for it."

In that posture, it was a clear copyright infringement. It was kind of obvious the guy knew about it, but it hadn't been proven as far you will go in a court of law. The judge just

wanted to get this thing off his office docket, and so he made this statement, "it's not relevant if you know there's a copyright infringement or not on your system. You can be liable for it if it's there."

My personal view is that this case is not going to be widely followed, because it's just a little too wacky; but it causes a lot of concern because it's reported in the law books, and these are the things that lawyers use as precedent when they're arguing new cases.

Something also happened the other way, and it seemed that copyright was starting to come out as a separate area from cases involving defamation or obscenity or other things. It seemed that somehow in copyright, like in cases of defamation or obscenity, if a distributor says they don't know that something's there, that's a defense. If they do know something's there then they have to do something about it; but if they don't know, it's a defense. It was starting to develop in copyright that even if you don't know something's there you could be liable, so now we have different kinds of rules for different kinds of illegal materials.

Now there's an ongoing case in California involving the Church of Scientology. There's a couple of cases, but I'm not going to get into the whole mess. The Church of Scientology seems to do legal actions in bunches, and there's other interesting things we won't get into unless you want to talk about it later. But there's this one case where they've been going after somebody who left the Church 12 or 13 years ago. He was a fairly high-level fellow and he's been fighting with them ever since. In his fight, what he started doing over the last few years was putting materials onto the Internet that were supposedly these sacred, copyrighted or secret Church materials, and so [the Church] went for an injunction in California Federal Court.

Now, they went for an injunction not only against this guy that they've been locked in this fight with for years, who was now pulling the Internet stunt on them, but also against the bulletin board that he was posting to and the Internet service provider that the bulletin board was getting to the Internet through. The Internet service provider was NETCOM. I forget the name of the bulletin board, but the Church of Scientology was suing all of them and asking the court to put an injunction against all of them so that the service provider and the bulletin board would have a legal obligation to keep things that were infringing on the Church's copyright from going out on the Internet.

There was a very early order when the case started up — the judge didn't know what was going on, and he kind of granted it for a few days against all the parties — that said they all have to not do it; but when it was re-argued a week or two later, and the Internet service provider and the bulletin board had a chance to say, "We're just distributors here," that distributor thing comes up again. The judge did make a distinction. He said that this guy, Dennis Erlich, can't post things that infringe on the Church's copyright. He has to know what's he's doing, and he can't do it. He might get away with some fair use, if he can show us what fair use is, but he basically can't infringe the Church's copyright.

The judge also said that he was not going to make any orders affecting the bulletin board or the Internet service provider. It's not their job to monitor what this other character does; the real fight is between the Church of Scientology and this guy. If there are identified materials that they're told to take off then fine, but they're not going to be put under a general monitoring obligation because one guy is supposedly putting copyright-infringing materials through the system.

The judge had mentioned the First Amendment in making this order, and again we're getting to a freedom of speech issue. The distributor is going to get in the same kind of trouble as the person, the individual, or the company that might be putting out the troublesome materials. That case is still going on, and it could turn again the other way, I suppose, depending on what is shown; but it is at least going in the other direction from the Playboy case which said that this thing that was very bothersome to on-line services.

By the way, it's very nice for property owners. There are two camps here; I guess I'm speaking on behalf of the on-line services a little bit, but for every on-line service that's annoyed by this there's a group like ASCAP or Paramount or somebody that loves it. [These groups feel that] everybody is supposed to go out and protect their property for them; and the on-line services say, "we're not in business to protect your property, we're in business to distribute information." That's kind of the field of play there.

There's another case going on right now in the Southern District of New York Federal Court, Manhattan, in the same courthouse — but not the same judge — where the [Cubby] versus CompuServe case happened. Over 100 music publishers are suing CompuServe because CompuServe users transferred some music files among themselves through the CompuServe system. CompuServe again says it doesn't know that they were doing this. The music publishers say CompuServe is liable for copyright infringement, and that one is still working its way through.

The most recent thing, I guess, is the famous White Paper on Copyright from the National Information Infrastructure Task Force on Copyright, which interestingly does not include the Copyright Office as one of the institutions involved in putting it out. It's more like it's coming from the Patent Office; I'm not sure why that all worked out that way, but it does. It suggests that on-line services should be held liable in some fashion for copyright infringements on the service. This is just a suggestion, and there's going to be quite a storm about this. Some senator, I think, very recently proposed a bill that would basically put into legislation everything proposed in the White Paper, so we're going to see some interesting fighting over that.

[There's also] other legislation attempting to impose obligations on system operators, and we're just going to mention this briefly. There's pornography legislation — I'm not going to get into it in detail at the moment — but there's a bunch of adult material legislation pending that's actually been voted in, but the final form of it has to be worked out by Congress. This may impose a lot of obligations on providers or on-line services, or it may be very light; that really depends on what these Congress people and lobbyists and politicians and whatever work out among themselves.

There was some anti-"bomb information" legislation introduced by Senator Feinstein a few months ago. After the Oklahoma City bombing — the fertilizer bombing involving a couple of farm boys or something — there were Internet terrorism hearings a couple weeks later, and these were apparently stimulated by this bombing. Distribution of bomb-making information on the Internet was the evil to be addressed. Even though this was not what was turning out to have happened in Oklahoma City, it seemed the pertinent place to bring this kind of subject up. There is some potential legislation that would put some type of obligation on on-line service providers to be careful about bomb information; if they have some idea it could fall into someone's hands and be turned into a bomb, they might be liable. That legislation is floating around at the moment, and there's a lot more coming. It's really up to the creativity and political advantage of whoever wants to propose such things, but we're going to see a lot more possible legislation and possible regulation of on-line systems.

Two more brief subjects. One of the real issues for system operators, one of the things that's really naughty, just really impossible to deal with the way things currently are, is that we're not dealing with one unitary set of rules. We're not dealing with just Federal rules — and even the Federal rules kind of contradict each other half the time. We're dealing with Federal rules in this country, in the United States, but we're also dealing with potentially up to 50 states with different rules. All the rules could work a little differently, and we've already seen, as with the case where the bulletin board in California was prosecuted in Tennessee, that a bulletin board in California — which is a fairly liberal state where they might get away with whatever adult materials they had there — can be subjected to the power of a court in Tennessee, which

might be a more repressive kind of state when it comes to adult materials. We've already seen this happen. That's just a first case. Anybody running an on-line system with a national coverage — which is pretty much anybody on the Web, for one thing — unless they're doing some very good filtering, if they're concerned at all about legal regulations applying to what they're doing they should be concerned about all the states and what they might be enacting from week to week, and how these things might be interpreted from week to week.

There's a kind of legal work called "Blue Sky" work that lawyers have done, like in the securities area, which we can use for an analogy to [the problem with] the different states. In a securities offering, when you raise money it is Federal securities laws that say what you have to do. Then, in every state where you're asking people for money, you also have to see if your offering is okay under the laws of that state. This is incredibly fact-intensive, drudging work, and in large firms they actually hire these Blue Sky specialists who do nothing but that for a couple of years. Now, that's just securities laws; just think if a system operator had to do Blue Sky work for every kind of legal regulation. Maybe not for everything, since copyright is just Federal; but [they'd have to do it for] adult materials, various kinds of criminal activities, privacy violations that might be a violation of one state but not another — things like that.

There's a lot of stuff to keep track of. I don't think any human lawyer can keep track of it, and if lawyers can't keep track of it it's hard expect people who aren't lawyers to keep track of it, and these are the people who really might be doing any of the monitoring. This is a problem that I have a feeling is going to manifest in some fashion, or a number of fashions, over a while. Generally, people are going to start understanding how intractable it is to have a lot of different sources of rules all applying to one place. One of the problems you get very fast is "the lowest common denominator" rule or "the most repressive regime" rule, which is that you can only have stuff on your system that's offensive to no one. Offensive to no one can mean attractive to no one also, and that's one of the paths down which the very disorderly legal scene is leading us right now. And this, again, gets multiplied by the facts that we have a lot of countries.

On a practical level, if I'm sitting plunk in the middle of the United States and I do something that offends the Thailand government, it's not very likely that anything's going to happen to me. They're not very likely going to be able to extradite, unless I was really some kind of weird terrorist or something. If it was just something that broke Thailand laws and somebody from Thailand happened to call in, on the practical level, on the exercise of state power level, they'll never get me. But there's a lot of companies and people that are operating on a multinational level that set up business associations and so forth. There was a case once where CompuServe had a game, *Wolfenstein 3-D* — which was the predecessor to the totally famous *Doom* game — which had a lot of Nazi imagery in it. Somewhere it became known that there's a German law that outlaws Nazi imagery in games and things like that, and even though no official accusation had been made by any German government or agency official, it all of a sudden looked like it was pretty risky to have *Wolfenstein 3-D* downloadable within Germany.

Almost all the system operators within the CompuServe system — and there are a lot of different areas — all got rid of *Wolfenstein 3-D*, which means it was no longer available not only in Germany but everywhere else, like here, where it's perfectly legal, at least on CompuServe. That was a forerunner. It didn't make any news or anything, but it was a good illustration of the kind of thing we're looking at and how another state's laws or another country's laws can lead to a heavy-duty repression of what we're finding on-line, and create a lot of confusion for system operators.

A lot of these issues are resolved with one's own members very simply and easily. To the extent that we're not just anonymously linking on the Web, we can have agreements with people if we have any kind of on-line service that we're selling to people. Agreements will

regulate your relationships with your own users; the question is, what about the rest of the world that doesn't have deals with you? What if there's something that they can sue you about? The issue remains no matter what you do with contracts.

I'll wrap up by saying, as an overview, that as the cases keep happening relating to system operator liability and new laws get proposed and worked on, there's a few questions that are going to come up over and over and there are themes that are going to keep surfacing. One is, are on-line systems important enough to protect from undue legal responsibilities? I would say that until a few years ago a lot of people would say they are not very important at all. There was a time they were considered so unimportant that when an MTV VJ said to MTV, "I want to use mtv.com for a domain name," they said, "What's that? Fine. Who cares? There's no money there." Of course, a year later they were fighting about it because all of a sudden on-line became important. On-line is becoming so important — and important to very large companies as well as small ones — that the importance of keeping them relatively unburdened is going to become a stronger and stronger theme, although it will be balanced against particular industry and special interest groups. If, at some point, it seems that an industry group has something to benefit from opposing rights for other groups, even if it's at slightly their own expense, they might do that.

Newspapers are an example. Newspapers have a lot of traditional legal benefits, and they're going on-line. To the extent that they can assert that those traditional legal benefits that were for newspapers as opposed to other businesses should keep going in an on-line world, you could actually see some fairly absurd distinctions attempted to be drawn between newspapers on-line and other companies on-line. Other companies on-line should be at some disadvantage because they are not the vaunted press, just as an example.

Another big question is whether monitoring obligations, in fact, create undue burdens for system operators. That's kind of the big, unanswered question. Everybody says, "Oh we can't monitor. It's impossible." It's easy to say. Is it true? Prodigy monitored for a while; Prodigy was also in the red, and actually only started turning a profit a year or two ago — and that's coincidentally when they stopped monitoring. So maybe monitoring obligations or monitoring activities do have a lot to do with how much money you can make. I mean, that just might be coincidence, but if anybody points to Prodigy and says, "Yeah, they did it. They did it and they were losing money at the same time," that's something, if there's ever a legal question that comes up.

Different services can do different monitoring. Some services — maybe lower-traffic services, based on what they're charging for what — can actually look at everything, and it may be that when a company running a service can look at everything and still make a profit, the law for those services may be that they're supposed to look at everything. That may be how it works out.

With other services there's no ghost of a chance that they can ever look at a lot of what's on there. Then the law for those services and what they do — which may not be at all the same as what the first kind of service does — will be that they don't have to look or they only have to look some. Would that be considered unfair treatment of different services? It would be hard to say. It depends on whether those distinctions that might end up being made actually make sense. I know I'm speaking very abstractly; we can talk more concretely about this in the question and answer session if you'd like.

Finally — and this is the part that I find difficult, because I never came up with an answer for this and it's tough to me — there are dangerous and illegal materials on-line. There are things that are national security breaches, and there are things that are morally depraved and all kinds of bad things, and it is socially desirable to have somebody pulling this stuff off when they can. It's a question of motivation and control.

If the system operators have the power to take it off, system operators are one of the few kinds of entities — maybe the only other, aside from the original poster — who can take the dangerous materials off the system. If you don't impose liability on the system operator, who's going to handle those illegal materials? Who's going to take it off the system? Who's going to prevent damage and injury and further damage and injury from occurring? So there's a question of social allocation of responsibility. Who is in the best position to do something about it? That can seem incredibly unfair if you're just trying to do some business, [to think] that you have this responsibility for stuff that's not even yours; but it may be kind of an accident of the kind of business it is, that if you're in the position of control you may be asked to take on that responsibility because you're the only person who can.

That's the end of my comments for now, and if we have some time at the end we can talk about other stuff. Thank you.

Ken Rosenthal: I'm going to just speak briefly about the subject of subpoenas and search warrants. As system operators you are the location of valuable information, and of lots of information. Information, in the criminal justice system in particular, is an important commodity. I spoke this morning, for those of you that were here, about the [Stephen Jackson Games] case; if you weren't here you may have heard about it. There have been a couple of highly publicized instances where law enforcement, seeking information, has used their powers of search and seizure to grab the computer system on which they felt information resides. What I want to talk about is what you do if you are confronted, if you are in the unfortunate position of being confronted with that situation.

There are a couple of things to understand. The Fourth Amendment is a critical part of our Constitutional Bill of Rights. When you study those procedural rights in law school or in history, you learn that they are a founding tenant of our government. In England they were searching, with general warrants, the homes of publishers of seditious material, so it's something that courts recognize as very fundamental. Fourth Amendment law has been construed to require government, unless there's an exceptional reason, to get a warrant before they go into a home and take material or go into a business and take material. But Fourth Amendment law has also been construed to mean that it's not necessary that the person whose home or business is being searched is a suspect in criminal activity.

There was a case involving the Stanford University *Daily* newspaper, back in the 70's, I believe, in which there had been an incident at the university hospital in which some university police officers were injured. It was reported in the paper, and based on the [newspaper] reports the university police surmised that the reporter had been in a location where he would have been able to see the perpetrators of this injury, and if he took photographs would have been able to photograph them. Pursuant to a search warrant, the *Stanford Daily* was searched, and their newspaper files were searched even though there was never any claim that they were involved in a crime.

Stanford Daily then brought a lawsuit against the university policemen saying that was a violation of their Fourth Amendment rights. [The newspaper said] that the rule should be under the Fourth Amendment, and if the government is going to go after somebody who is not accused of a crime to gather evidence in order to prepare a case, they should be required to use a subpoena and not a search warrant. The district court upheld that right, and said if we're going to allow government, by force, to go in and take information and intrude on the privacy of non-criminal citizens, they should use the less intrusive means of a subpoena.

I'm going to talk this afternoon primarily about why that is less intrusive, and what the differences are. Unfortunately, the U.S. Supreme Court said that's ridiculous, that there's

nothing in our Fourth Amendment or our prior case law that says the government has to proceed by subpoena rather than by search warrant.

In fact, under the Electronic Communications and Privacy Act, there is some suggestion, as I read it, that government doesn't even have that option when they're going after stored electronic data that's less than six months old — they have to use a search warrant rather than a subpoena.

So let's suppose that, for whatever reason, there has been a search warrant issued that identifies your computer system as a location that should be searched. What is likely to happen under that scenario? What is likely to happen is that you will get no prior notice of the fact that a search warrant is coming. Although there's no claim that your system itself was involved in crime, you will be faced with the unhappy situation of policemen arriving at your door. The first thing you should do before you let them in is see whether they have a legal authority to do so, and under our Fourth Amendment they have to have a warrant from a court unless there's exigent circumstances. It would be unlikely in the extreme that there would be exigent circumstances involving the data on a computer system, so they have to have a warrant and you're entitled to see that warrant.

But if they have a warrant, they're entitled to come in and they're entitled to search for what that warrant authorizes them to search for. You're not entitled to very much at that point, which is the problem with the search warrant as opposed to a subpoena — that is, you will have had absolutely no input into what they're searching for and how the warrant is worded. I included this in the materials that some of you may have gotten from this morning, and if you haven't gotten them all registrants will be getting a CD-ROM within three weeks of this date which will have all of the materials from all of the seminars on them. Unfortunately, we don't have excess copies of the material that quotes from the search warrant that was used in the [Stephen Jackson Games] case, and it's extremely broad.

Pursuant to that warrant, police officers and federal agents went into the bulletin board's last publisher in Austin, Texas and took their bulletin board system, their computers — that shut them down — and in addition to their computers they took a lot of other stuff that couldn't have had, by any stretch, the information they were looking for. It's a crime in virtually every jurisdiction to interfere with the execution of a search warrant, so you'll have to understand that as outrageous as it may be, the time that you're going to litigate this and you're going to challenge this is going to be when you can get a lawyer on the scene, perhaps at that moment or afterwards in civil court.

I'm going to come back to the search warrant situation, but I just want to contrast that with the subpoena. A subpoena is something that may be issued by law enforcement to gather data, but if you should be fortunate enough to be served with a subpoena rather than a search warrant, you have many more options.

Number one, there's a time within which you need to respond to that subpoena. That gives you time to get in touch with a lawyer, and it gives you time for you and your lawyer to get in touch with the U.S. Attorney or the agent who's referenced on that subpoena and negotiate with them or talk to them about why that subpoena may be too broad. If you're not satisfied with the results you get to go into a court — whether it's U.S. district court or whatever court has jurisdiction over this case or this investigation — and move to quash the subpoena or limit the subpoena. Furthermore, if you're faced with a subpoena the person who's going to search for and collect the data, and who's going to furnish it to the government, is going to be you, the person who knows what your computer system is about and knows the difference between a computer disk and a printer or modem. Printers and modems were seized as well on the [Stephen Jackson Games] case, even though there was nothing they could have had on them.

Let's go back, then, to the search warrant situation — which, unfortunately, is the situation you're probably going to be faced with if for some reason your location is the location where the government thinks there is evidence of a crime. As I said, when the search happens you are not going to have much advance notice. That's not always the case, but assuming that is the case your options then are — after the fact, and after the damage has been done as it was in this Stephen Jackson Games case — to go to the law enforcement agency that has the equipment, the documents, the evidence, whatever it was that they seized, and try to get it back. There are procedures for filing motions for return of property even if you're not a party to the action in these situations, but there are also ways that you can hopefully negotiate.

Unfortunately, once law enforcement gets its hands on the evidence they are very concerned — as we learned recently in the most publicized criminal case in quite a while — about the fact that there's going to be a defense lawyer on the other side who is going to be challenging whether it's the best evidence, whether there's a chain of custody, and whether the evidence is admissible in court. They are going to have to “process” this evidence before you get it back, even though you're not involved. That's obviously a situation where you need to get someone involved who can represent you to try and persuade the powers-that-be that they have seized too much, that the warrant is too broad, and that there are legal consequences that may follow from the fact that they haven't complied with the requirements of law.

In addition to the Fourth Amendment requirements, when you are involved with electronic communications there is a statute that governs this, and it is a very complicated statute. It is the Electronic Communications and Privacy Act, and that statute sets out requirements not only for warrants but also for what's called “super warrants” when there are certain kinds of documents that government is seeking. I'm not going to try and go through that statute, but just indicate that there are provisions under that statute, as well as other actions, that can be brought which entitle you to damages after the fact — for what good it will do you — and for violations of the requirements of the Electronic Communications and Privacy Act. There are also requirements that law enforcement will hopefully be persuaded to observe as time goes by in the seeking of this kind of information.

One of those requirements relates to the fact that there are different categories of electronic information, and there are different procedures that must be followed in seeking to get them. What [Stephen Jackson Games] sought to do, and was successful in doing in the case that I mentioned before, was in bringing a civil action pointing out that the government had violated provisions not only of that act but of a privacy protection act. [Stephen Jackson Games] was deemed the publisher and was able to get substantial damages and attorney's fees for the seizure of their equipment. The bad news is that they weren't able to do it for months and months, and despite the fact that they had attorneys involved and they had political figures involved they were without the use of their equipment for a long period of time. Hopefully these things don't happen too often; but my purpose at this point was just to outline the steps that are likely to be followed, or at least what you can expect.

I think what I'm going to do at this point is turn to a question and answer period to see what, if anything, we need to talk about in terms of the Electronic Privacy Act or the search warrant procedure.

Our goal here was to try to leave enough time for questions so that people's concerns could be responded to.

Lance Rose: Okay. Over there.

M: [inaudible]

Lance Rose: The question is, is there some kind of legal problem of liability if somebody points at somebody else with a Web link and the person that is pointed to has a problem with it?

M: To give you an example, I represent an insurance company and somebody created a Web link that [inaudible] this book form and sent it.

Lance Rose: Okay, this man is with an insurance company with a Web site, and somebody out there in left field gave people a form and said, "fill this form out and send it to that Web site and the insurance company will give you a quote," even though there was no arrangement between the two companies.

This is actually a good case because there is no legal right to sever Web links, per se. There is no such thing as a law that says you can't link to my site. You've got to hang it on something else, something else that people have said to be doing wrong. In a case like this — if one company says that if you send something to another company they'll do something for you — as the intellectual property lawyer that I am, the first thing I think of is a law called Section 43(a) of the Lanham Act, which is mostly a trademark law. It's a federal trademark law, and part of that law goes beyond trademarks and says that any time a company says something false about its own products or about another company's products, when it's talking about another company then that company can sue it under the law.

If your insurance company, speaking hypothetically — this is not official legal advice, of course — if an insurance company felt that another company was saying false things about it, the false statement being, "send quote forms to this company and they'll help you out with them," that's a false statement about what your company will do. That would seem to me to lie very well within a trademark-style Lanham Act kind of claim. It is also an example of what would happen, in general, with a Web claim. If there is an objection to someone linking, you can't go to a court and say, "I don't want that person linking. They can't link to me." You have to have something more going on, such as a misrepresentation in a competitive situation or some kind of defamation or some kind of false association with some disreputable site or something. It has to go beyond the mere distasteful linking.

[Tape change]

Lance Rose: I thought I understood that question at first. The question started out being, "do the same laws of libel and slander apply in the on-line media as in the print media?" The short answer is "yes," but are you talking about a place where anybody can come in and put in their two cents, or are you talking about a published situation?

M: [inaudible]

Lance Rose: Okay. If you're running an area where anybody can come in and post messages, and you're the person running the area and you don't want them there, that's not really the law of libel, that's the law of owning your own press, so to speak. If you don't want somebody to be using your forum as a place for their speech and you are the proprietor, you have that right. This actually came up in our morning session; around the edges of this there is a little bit of legal development that has to do with shopping centers and has to do with state constitutional rights of free speech — not federal, but state constitutional free speech rights. It has been held, in a number of states — a small number, like five or six — that, for instance, shopping center parking lots can be used by people who are doing political leafleting because these are places

where the public tends to gather in that local area. The town center is gone, so the mall takes its place. But these are under state constitutions, and shopping centers and malls are historically well-established things.

The on-line world, as it were, is just starting. It would be very hard to convince the court that any one on-line forum is so predominant, so ubiquitous, that people with a certain message legally have to be given access to that place to give their message as opposed to just starting up their own Web site or starting up their own bulletin board. I suppose there was a threat, for a hot minute, that the Microsoft network was going to be that place; but that doesn't really seem to be turning out that way for now.

M: [inaudible]

Lance Rose: I'm going to have to ask for a little more clarity. The question so far is, at a corporation or university Home Page, does a disclaimer release them from liability? I need more detail for that question.

M: [inaudible]

Lance Rose: Okay, are you saying, for instance, that if a university has a Web site and students can publish pages on that site, can the university exempt itself from liability by disclaiming any connection between itself and the students posting at the site?

M: Which they are enabling them to do.

Lance Rose: It could help. What you're doing, when you get into that kind of Web site operation, you are actually starting to get very close to that CompuServe vs. [Cubby] situation. Again, in the CompuServe case, there was a newsletter being published through CompuServe, and CompuServe said it wasn't specifically aware of the contents of every issue of that newsletter. The court believed it — I guess it was a believable statement — and said, "CompuServe, you're not responsible for everything that you don't know about that's on your system."

I think that applies in a university Web site with Web pages published by its students, especially if the students can refresh any time. The university could very easily say, "I didn't know what the person put up there today, that little rat," and thus distance themselves from the student. That's what the disclaimer is, to distance themselves from the little reprobates.

Yes, a disclaimer would help but it wouldn't settle the issue. If the university, in fact, knew everything that was going on — let's say they had a highly-moderated site, and all pages had to go through some university functionary who checked the pages. The disclaimer to the public is not going to take away the responsibility they have kind of taken on already themselves, as editors, so you have to look at the whole operation. The disclaimer statement alone is not going to do the trick one way or the other.

We've got to go. I guess we can talk on the side, but this general session is over. Thank you.

Wayne Martino: We have some handout materials; there's not enough to go around, because there's a lot larger crowd than we thought was going to be here. We're going to put them out. There's only about 20. All of the material that's here, if you were here for the morning session, it is already incorporated in the morning book that was handed out. If anybody would like these materials — and what they are is articles on making and enforcing electronic contracts and the

legal aspects of e-mail — if anyone would like those materials I'll send them to you by e-mail.
My address is wmartino@callnet.com.

INTERNET LEGAL DOING BUSINESS IN CYBERSPACE

MODERATOR

Wayne Martino, Esq., P.C.
Brenner, Saltzman & Wallman

SPEAKER

George Brencher, Esq.
Brenner, Saltzman & Wallman

Wayne Martino: This session is on “Doing Business in Cyberspace.” We’re going to cover a bunch of different topical areas today. The first one will be on making and enforcing electronic contracts. We’ll then talk about member agreements and content provider agreements very quickly; Margie Seif from AT&T was supposed to do that, but unfortunately she had to go as well, so I’ll run through that for you. We will then talk about emerging issues and the legal aspects of using e-mail.

I’d like to now introduce George Brencher. He’s an associate at Brenner, Saltzman & Wallman in Newhaven, Connecticut. George is a graduate of Penn University and Penn Law School, and he had previously clerked for José Cabranas, the Chief District Judge in the State of Connecticut. George.

George Brencher: Good afternoon. We’ll be talking this afternoon about making and enforcing electronic contracts. For those of you who have a great deal of legal training some of it may be a bit tiresome; but for those of you who haven’t, I think it will be helpful.

As commercial use of the Internet, on-line services and electronic messaging systems grows, you’ll see more and more business transactions being carried on in cyberspace rather than in the real world. Increasingly, these transactions will result in electronic rather than traditional paper contracts. This discussion is intended to analyze several types of electronic contracting situations in terms of traditional principles of contract law.

There are five types of electronic contracts that we’re going to be looking at: electronic data interchange, or EDI; the on-line licensing of computer software; the on-line sale of goods; the provision of on-line services; and what I call “negotiated” contracts.

Before looking at these specific contracts I’m going to go through some of the basics of contract law. I hope it doesn’t bring back any unpleasant memories for those of you who’ve been to law school...

The first question relevant to the basics of contract law is, “what is a contract?” Put simply, a contract is an agreement between two parties that the law will enforce; it is a promise or a set of promises that the law will recognize. There are a variety of legal rules that govern whether contracts are enforceable, and there are really two main sources of such rules.

The first is the Common Law, and the second is the Uniform Commercial Code, or UCC. The Common Law is the judge-made law of legal cases that’s mostly what you’ve been hearing discussed today in other contexts. The Common Law has been collected and summarized and organized in what are known as “Restatements” on a couple of occasions, and the basic source of contract law is called the “Restatement of Contracts.” The Restatement doesn’t really cover the entire ground, because the UCC governs the sales of goods. The UCC is a statute — it’s a model statute, adopted in every state other than Louisiana in some form or another.

First you’re going to get a little bit of background governing contract formation. For a contract to be formed the parties must reach an agreement to which they mutually assent.

Lawyers often use the phrase “a meeting of the minds” to describe this concept of mutual assent. The basic concept of mutual assent is that the parties must clearly understand each other, and the subject matter of their agreement, in order for a contract to be said to exist. The process of reaching a meeting of the minds takes place through what lawyers refer to as “offer and acceptance.” In other words, one party proposes a bargain — that’s the offer — and the other party accepts the bargain — that’s the acceptance. This kind of a framework sounds quite simplistic, but it’s useful in analyzing some of the issues that arise in on-line contracts.

The second legal concept that’s relevant in the on-line circumstance is known as the Statute of Frauds. Most people are familiar with the concept that legal contracts, in order to be enforced, must be in writing. It is not entirely accurate, but it is true for some contracts. The modern version of this concept is found in both the UCC and the Restatement, and in its modern version the Statute of Frauds requires contracts to be in writing and to be signed by the parties in order to be enforceable. It doesn’t apply to all contracts, however. It does apply to contracts dealing with land, contracts for the sale of goods with a price of more than \$500 and contracts which by their terms cannot be performed within one year. In its evolved form the Statute of Frauds has kind of loosened up quite a bit. Law students spend a tremendous amount of time studying the early application of the Statute of Frauds, which was quite strict.

However, as new technology has evolved and new business practices have evolved, courts and commentators have been somewhat flexible with both requirements. For example, it’s no longer the case that every term of a contract needs to be set forth in writing. Now only the essential terms need to be set forth, and an actual signature is not necessarily required; what is required is a symbol or some other means of authentication that identifies the party against whom the contract is going to be enforced.

Some examples of the technology that has not been really impeded by the Statute of Frauds are telexes, telegraphs, and to a certain extent faxes, although there is some uncertainty about the applicability of the Statute of Frauds to faxes. There haven’t been any reported cases that I know of that actually validate the use of faxes for entering into contracts.

Now, about the various types of electronic contracts we’re going to be talking about... The first one is “electronic data interchange,” or EDI. It’s probably the least interesting from a contract law perspective, but it’s also sort of the most commonly used type of transaction now. It may be the most dominant use of computer technology and networking technology for commercial applications that we have; it’s really an essential part of “just in time” manufacturing and that sort of thing.

The chief characteristic of EDI, and the thing that really makes it somewhat less challenging from a contract perspective, is that the parties to EDI transactions generally agree in advance on a structure and procedure for carrying out their on-line transactions, and they frequently do this in a written document that they refer to as a “trading partner agreement.”

Various legal groups have published model trading partner agreements, including the American Bar Association, if you should be interested. Because the parties have entered into this written agreement in advance, EDI transactions are pretty well-structured. They’ve set out agreed-upon procedures for communicating, for example, purchase orders and acceptances of purchase orders, and the electronic aspect of EDI for that purpose is really almost an aside. It’s sort of a fulfillment of the written contracts terms; that means that offer and acceptance is really not a problem in the EDI context. The Statute of Frauds is probably not an issue either, partially because so much of EDI transactions are executed on a computer-to-computer basis without human intervention. The model trading partner agreement, and most trading partner agreements actually used out there in the field, have very detailed record-keeping and audit procedures, so that when a court goes to look at what the written backup for the transaction

is, the parties can produce these very, very well-documented electronic records of all the trades. That probably satisfies the Statute of Frauds requirement for writing.

With respect to the signature requirement, again you have a lot of computer-to-computer interaction in EDI, and there are very sophisticated authentication procedures built into that, and courts are probably likely to accept those kind of authentication procedures as sufficient for Statute of Fraud purposes.

The next kind of contract we'll be talking about is on-line software licensing. This is becoming more and more common. I haven't had a chance to check out the Web site, but I assume that this is what Microsoft is going to be doing as they start selling their software applications through resellers over the Internet. It's probably going to become the alternative of choice for many manufacturers to "shrink-wrap" licensing.

Probably most of you are familiar with shrink-wrap licenses, the licenses that are printed on the inside of the software packaging, or sometimes on the envelope holding the CD-ROM or the disc. There's usually a statement on there that says if you break the seal on the envelope or the packaging, or if you install it in your computer, you are then accepting the terms of all of that fine print in the license. Shrink-wrap licenses were originally developed as an alternative to entering into written agreements because it was really impractical for software manufacturers to require the purchasers of the software to actually enter into written agreements.

Unfortunately for the software manufacturers, shrink-wrap licenses raise a large number of enforceability issues, and looking at these issues will help us understand a bit about some of the issues that will arise in the on-line context.

The first of the issues arising with shrink-wrap licenses is the fact that the purchaser of the software never sees the terms of the shrink-wrap license until after they bring the box home and open it up and go to install it on their computer. If you think about the offer and acceptance concept, that's a little bit like me agreeing to sell Wayne my bike for \$100, him paying me \$100 and taking the bike home, and then me calling him a couple of hours later and saying, "oh yeah, by the way I get to use it on Mondays and Wednesdays." You know, it's really hard to say that somehow this purchaser reached a meeting of the minds with the manufacturer on the terms of this software license if it was encased in the packaging and they paid for it before they got to read the license.

The second issue is the sort of ambiguous acceptance of those terms. Obviously, breaking a seal on an envelope or installing a disk in your computer system is somewhat less of a definite agreement to a contract than signing on the bottom line. In the software licensing context this is particularly significant, since one of the primary purposes of software licenses is to contain limitations of warranty, limitations of liability, the kind of damages you can recover from the software manufacturer if the software has bugs in it.

Typically, in consumer law those kinds of provisions in a contract need to be open and conspicuous. The manufacturer, in order to enforce them, has to be able to demonstrate clearly that the consumer saw these things and was aware of them when they entered into the transaction. They're sort of buried down on the bottom line in that envelope that holds the disc, and there is a serious question as to whether or not the software manufacturers will be able to enforce those kinds of limitations. As for the Statute of Frauds issue, it's not significant in the shrink-wrap license areas, since most software that's licensed in that fashion is under \$500 in price, and so not necessarily within the Statute of Frauds.

If you take what we know now about shrink-wrap licenses and you apply that to the on-line registration of software, you see that some of these problems can be taken care of, though it depends a bit on the structure of the on-line's registration arrangement. If the purchaser is only registering the software on-line and not buying the software on-line, you never really get rid of the problem of the purchaser going out, paying their \$150, coming home, putting it on

the computer and then finding that they're faced with a sort of take-it-or-leave-it situation with the terms of the license. Obviously, if the software is being purchased on-line, what you want to do is show the software purchaser all the terms and conditions before they commit to paying, that way it's part of the sale transaction.

If you're concerned about the ambiguity of acceptance that you get from breaking a seal or installing a disk, you can solve that in the on-line context by requiring some kind of obvious action of acceptance, like having the purchaser type "I accept" at the bottom of the screen when they register the software, and keeping an electronic record of that transaction so that you can later produce it to show that they've definitely agreed to those terms. Again, if you're going to use limitations on warranties and that sort of thing, those things should be open and conspicuous.

With respect to the Statute of Frauds, it's to the extent that it's relevant because you're talking about things over \$500. It may be difficult to satisfy on the on-line context because there's really no paper record, but if you look at the EDI context, it may be possible to convince a court that your record-keeping measures are sufficient, your electronic record-keeping methods are sufficient, and that this is really a trustworthy record of the transaction.

Turning now to the on-line sale of goods, it's really a similar analysis to on-line software registration, where you're selling the software on-line. It's easy to make the terms of the purchase visible up front to the purchaser. It's easy to keep a record of their affirmative assent to those terms. If your payment mechanism is other than on-line, you can then send them a hard copy of the terms and conditions when you send them an invoice or some other request for payment. This again will solve the Statute of Frauds issues, because you will have reduced it to at least something in writing which you have provided to the purchaser. If you provide this writing to the purchaser and then they then send in their payment, it's pretty clear that they've agreed to those terms.

If payment is made on-line, one idea is to then send a copy of those terms and conditions to the purchaser by e-mail, so that you can at least use something that a court may find more familiar as a means of memorializing the terms in something closer to a writing. But, in general, the Statute of Frauds should be no more of a problem on the on-line goods situation than it is on the on-line registration situation.

The next transaction we'll discuss is the provision of on-line services. You're seeing providers of on-line services moving more and more toward purely electronic contracts. A lot of earlier contracts are written that contain pointers to electronics terms of service, and things like that may change from time to time. I'm not really concerned with that, because then you're really looking at a written agreement; what I'm really concerned with here is a purely electronic transaction. The main issue for these kinds of transactions is that the users of the service have an opportunity to see the terms of service before they enter into the transaction, and review the content, and then you can record their acceptance electronically. Whether or not you require this review and acceptance before you show them the material depends a lot on a balance between their inconvenience and your desire to ever enforce that agreement, and that's a decision that you really have to make as a business matter.

In a subscriber-based service where you're going to be sending them some kind of request for payment, obviously you can follow up with a written [copy] or e-mail [with the] terms of service. In an open scenario, where you're going to be providing services free of charge — on a Web site, for example — demonstrating acceptance is pretty difficult, although there is one feature of a lot of Web sites that I do want to touch on, and that is what some people are referring to as "Web wraps." These are sort of the terms of licensing and terms of use that you see in Web pages.

Most of the time they're only accessible if you go all the way down to the bottom of that Web page, and you go through a link on the copyright notice, and then all of a sudden there's a two or three screen listing of terms and conditions. The enforceability of these terms and conditions is probably weak; they're certainly not open and conspicuous to the extent that you're looking to limit liability or have disclaimers. As part of preparing for this, I kind of went out to see what some people were doing on big commercial Web sites.

I had a hard time finding the terms and conditions. The idea that they're hard to find even if you know they're there suggests that people who are supposed to be bound — who aren't supposed to know they're there — probably aren't finding them very easily. If you have a site where you think that these things are important you're going to have to try to make it a little bit more conspicuous, so that you could demonstrate that people actually saw these things if you want to enforce them.

The Statute of Frauds really is not an issue with the provision of on-line services because it generally does not apply to service contracts, particularly short-term service contracts.

The last category of agreements I'm going to talk about is what you can refer to as "negotiated agreements." Negotiated agreements — really what we are talking about has been sort of "form" contracts, very simple transactions — you want to buy this software, you want to access this database. Negotiated agreements are what I mean by what are more complicated business transactions, ones that would actually be negotiated between the parties. The back-and-forth negotiation is increasingly taking place on-line, where parties are doing these things through e-mail. The important thing in that context is that when you get to the end, and everybody thinks they've reached an agreement, that both parties agree on an identical document. The fact that you've been sending drafts back and forth in a variety of messages can be a problem for each of the parties to demonstrate that the other party agreed to that identical document. Really, the thing to do is to make use of encryption technology for this purpose; and I'm not going to get into encryption technology, but there are a wealth of terrific articles for lawyers and others on practical applications of encryption for doing negotiated agreements on-line.

Finally — and I'm not really going to get into these issues — but if you look in your written materials, I've talked a little bit about some of the proposed revisions to Article II of the UCC, which impacts on some of the issues that I've just gone through, as well as some recent digital signature legislation. I think that the proposed revisions will ultimately take care of some of the problems that we've talked about, particularly in the software licensing area.

The problem is, if you're not familiar with how the UCC works — a group of commissioners get together, they draft legislation, they circulate it. They get comments, they revise it. That usually takes a year or more, and then they come out with a final recommendation and it's up to all of the various state legislatures to choose to adopt or not adopt all or some of that statute. So if you're looking at it realistically, it's going to be quite some time before the revised Article II actually comes into play — if at all.

And with respect to digital signature legislation, two states have enacted digital signature legislation in this past year: Wyoming and Utah. The statutes aren't very long or very complicated, and if you're interested in the topic it's certainly worth looking into.

Wayne Martino: (Just hold on a second. I've got to move to a different presentation.) I thought that I would run through a "membership agreement and conditional-use policy," and then a "content provider agreement," just as an example of the implications of some of the things that are contained in the agreements, and why.

The first is the membership agreement, and the other is the conditional-use policies that many of you are familiar with when you sign on to on-line services. I think George's point of the

enforceability of the terms and conditions that I'm going to talk about is still an open question as to whether or not people are really manifesting any assent; many times there's no opportunity to either review them before the person signs on to the system, or it's difficult to find. There probably will be some litigation over this; there'll probably be some litigation over whether it's enforceable as a contract of adhesion. Those areas really aren't settled yet, but I'm sure that in the near future that they will be.

The contents of those agreements will... The major issues will be as follows: the first one is going to be the limitations on the user. What activities do you not want going on if you're a system provider, or if you're providing a bulletin board for people to access? They're pretty well settled as to what they don't want you to do; they don't want any defamatory harassing or illegal conduct. Quite simply, they could potentially be liable for that. There are some decisions out there in the "[Cubby] versus CompuServe" and the "Stratton-Oakmont" that go in different directions as to whether or not there is liability, but there is a concern in that area that they will prohibit you from making those types of uses.

They are also concerned about copyright infringing and whether or not they become responsible under a strict liability theory for copyright infringement. They will tell you that they don't want you putting anything on their system if you don't have permission; in some instances you may actually find people telling you that they don't care whether you have permission or not, they don't want you putting anybody else's copyrighted material on unless you provide them with permission.

The pornography, obscene materials — this is again depending on what the orientation of the system may be, but many of them will prohibit you from doing that for a variety of reasons, probably the most important of which is to the extent that you not specifically dedicate it to that use. They don't want it on their system.

And the last one is that many of the agreements will contain provisions that eliminate any advertising, solicitation or promotion. Basically, you will see people saying they don't want you to go and advertise on our site, and if you want to do that you've got to pay for it.

The next section of those agreements is generally the reservation of rights of the operator. The first one is their ability to monitor and edit content; that's becoming a real hot issue now, both from a First Amendment point of view, as to whether or not they can do that, but more importantly, if they do that, whether or not they potentially have liability. Again, the decision of Stratton-Oakmont — which, even though the case has been withdrawn, the decision is still out there — suggested they may be publishers and not distributors, and therefore may have some liability for that.

One of the emerging areas is whether or not the information about a user's habits are going to be available. It's an emerging issue right now as to whether or not, not necessarily what individual people do, but whether or not how many people go to visit what sites, and what kind of demographic information will be available. I'm seeing companies go different ways on that as to whether they want to include or don't want to include that term that says that they can use that information. I think some of the more enlightened ones are giving people the right to opt out of that, so that among other things, there are people who are not finding e-mail about specific topical areas because they visited certain areas.

The last one is a pretty clear one; that they generally will retain the ability to restrict your access or to terminate it.

With respect to the content, there are some very simple issues. [The first is] who owns the content. Generally, the system providers will say that anything you post to our system is owned by us, and you don't retain any rights to it. Maybe a right to use it yourself, but in terms of our right, the system operator's right to republish it, they'll maintain that. They will tell you that anything that you find on their system, they don't want you having any right to reproduce it

for commercial purposes; they want those rights for themselves, so they will limit you there. And they will also tell you that they are not responsible for any third-party content — although you're seeing now that CompuServe, I think, just announced that they're going to create a site that will be a "family" site, and that they're going to monitor it. It's going to be interesting to see how they do that, and if they're successful.

The next section of the agreement that George had touched on is the limitation of liabilities, and I'll quickly run through these. Maybe we start with the concept of (unintelligible) in larger print, and bold. There's a concept that it's got to be open and conspicuous in order for it to be enforceable, and generally you'll see it in bold, you'll see it in large print so that it differentiates it from the remainder of the agreement, so that you can in fact try to get yourself out of liabilities.

This area may be probably one of the more critical areas in terms of enforceability that a systems operator, or somebody who's operating the cyberpeople, are opposed to and is going to be concerned about, especially if they are providing the service for free. They will generally indicate that they should be there, and that they're not a publisher; they will also indicate that it's on an as-is-available basis. [They'll indicate that] there could be bugs in the system, and that things may happen, and we're not guaranteeing to you that it's going to remain on-line the entire time. They will also try to exclude their liability for third-party actions, and will also attempt to limit their damages to indicate that they're not responsible for special or consequential damages. They may also indicate that the damages are limited to a certain dollar amount, possibly what they were paid, if they were paid for the service.

The last two items: I think you're seeing more and more of having an internal statute of limitations — one that will limit the time period that anybody can ever bring a claim against them, and not rely on UCC provisions or other state law provisions that could make the time period anywhere from two years to six years.

And the last area that you'll see in contracts is a choice of law, arbitration and jurisdictional issue. What law is going to govern this contract? You've got users who may be anywhere in the world. The systems operators will generally try to include a choice of what law is going to govern; I would suggest to people that if there's a possibility of any real litigation they try to do it through arbitration, for a variety of reasons. It's probably less expensive, but certainly it's going to be private; and if you're a large provider, I'd suggest to you that that's a good way to proceed. I think it's been successful in other areas, in the securities areas, for example, where the industry basically said, "we're going to arbitrate as much of this as we can through a member of [inaudible]." I would suggest that you do that.

The last thing is a question of jurisdiction, which we'll get into later. If you're a provider, where can you be sued? The way that many people are doing business on the Net right now is to be content providers.

And I'm just going to quickly run through the terms of those agreements, or at least the major terms of what agreements they're going to have with people that are providing content on their system. The first one is how long is the agreement going to be for, and under what circumstances it can be terminated. Can the agreement be terminated at will by either side, or are there going to be quantitative reasons? For example, there may be dollar numbers that are involved that says we've got to make certain dollars off your site or we don't want your content; or there may be qualitative reasons that they may try to incorporate into the agreement, [that say] under what provisions they can terminate you.

The obligations of the purchaser will be to manage the area to the extent that they are editing or facilitating communication between those people that are doing the system, and to promote it. There may be requirements that they do some promotional activities and enforce the policies. To the extent that anybody here is a content provider, I think the enforcement of

policy [is what] you've got to be very concerned about, because that's potential liability for you even though the "deep pocket" may be the systems operator.

What you will see in these agreements is that if you're responsible for monitoring the content, you've got to be vigilant about that and about enforcing their policies, not only from a termination point of view but from a liability point of view. You'll also see in these agreements that there'll be indemnification provisions, where they will ask the content provider to indemnify them to the extent that if they ever post bad material, they failed to adhere to the policies. The same limitations on liabilities that I had spoken about earlier would be included on this, and generally they'll go one way. The systems operator will say, "I'm not liable for everything, and we'll try to make the content provider liable for everything." Again, as the Net is becoming more and more content-oriented, tying somebody up and having them be only on your system, and providing your content, is good to the extent that you are allowing them to build a following. This may be a very important revision, as well; once the relationship terminates, can they go out and do this for somebody else? Is there a "cooling off" period, during which they cannot maintain the same type of forum that they had maintained yours?

With respect to content ownership, I've seen it go both ways. I think it's more likely that the content... In this one, whoever is providing and monitoring the forum is going to own it. That's a little bit hollow, because the system's operators basically are going to say, "yeah, you can own it, but what we're going to do is take a license to use it for whatever purposes that we want." So to some extent there may be some dual ownership.

One of the last items is confidentiality, whether or not you want to have a provision in there that they're not going to talk about the terms and conditions of the agreement. Again, to the extent that this is becoming competitive, a competitive marketplace for content, confidentiality becomes more important.

And the last issue is the choice of law, arbitration or jurisdiction. With content providers, these types of agreements are probably a lot more enforceable because generally they are negotiated contracts.

I think what we're going to do now is turn to the legal aspects of using e-mail. We're going to talk a little bit about the legal aspects of using e-mail. It may be one of the less glamorous topics today, but if you are a business that makes extensive use of e-mail, it's probably something that is worth thinking about.

Obviously, the use of e-mail by all kinds of business people, lawyers included, is becoming increasingly popular. I have seen figures as high as 25 million e-mail users out there. The practical benefits of e-mail are obvious; probably everyone here has used it extensively, and can appreciate how nice a tool it is to have at your disposal. However, there are a couple of concerns worth thinking about in the use of e-mail by a business organization, and these are concerns that may not be something that business managers might necessarily have thought about a whole lot.

I really think that two chief concerns are the fact that e-mail is discoverable in litigation, and also some of the security risks associated with using e-mail, depending upon the configuration of your e-mail system. I'm going to look at both of those two and then touch on a few diverse topics that are of concern.

A lot of people don't realize that e-mail is discoverable in litigation. It's really unlike any other... It's quite alike with all other communications that you might have in your business organization — memos, letters, telephone calls, that sort of thing. And it's not necessarily the written portion of the e-mail that's going to be produced; you're going to find that people are going to be either asking you — or compelling you — to go into your electronic records, your backups, and your archives, including traces of deleted and erased e-mail messages, and producing those things for litigation. Many of you probably remember this was a feature of the

Iran-Contra investigation quite a few years ago; unfortunately, it is no longer limited to those kinds of exotic cases.

If you read litigator newsletters, you see that this is becoming more and more a hot topic among litigators out there doing employment litigation and other things like that. There are a few practical assets of this discoverability; the first is that e-mail may outlast paper. If you haven't integrated your e-mail system into your normal document destruction policy, you're going to find that there are e-mails out there over time that may outlast the kind of paper records that you normally would have gone and destroyed. And again, the fact that you can go and capture these erased or deleted e-mails makes them somewhat different than paper, although word processing systems can pose some of the same threats.

The fact that e-mail is discoverable probably means that business organizations ought to think a little bit more about it in terms of a letter rather than a telephone conversation. The record of it lasts a lot longer than a telephone conversation that's written down. I'm not saying that you have to treat e-mail like some kind of a formal means of communication, but it's true that there are some things that you wouldn't say in a letter and there are probably some things that you shouldn't say in e-mail, that you might otherwise be inclined to put in e-mail because you think it's just kind of a quick, easy and passing thing. There's sort of a psychological interface with e-mail that leads people to think of it as a very casual communications medium.

A lot of companies have found out the hard way when some of those e-mails have been produced in litigation that perhaps they should have thought more carefully about what was going into the e-mails, particularly in employment litigation. There are a variety of security issues involved in using e-mail; I'm going to just really touch the surface.

Obviously, businesses use e-mail to transmit all kinds of sensitive confidential information, including trade secrets and other things which, if they were disclosed, would pose significant problems. A lot of the people who are doing this don't necessarily appreciate that there are some security risks associated with putting those things in an e-mail that may not be the kind of security risks associated with putting them in a Federal Express envelope, for example. Obviously, e-mail is subject to a risk of interception by third parties, and this is the kind of interception that could occur without being noticed by the sender or the recipient. Obviously, if your Federal Express package arrives and it's been opened, or it doesn't arrive at all, you might have some reason to believe that it was intercepted along the way; with your e-mail message you may not be able to tell that. The [inaudible] which a variety of different speakers have touched on today is really the starting point for assessing the security of e-mail.

As Ken [Rosenthal of Brenner, Saltzman and Wallman] mentioned in the last session, the [inaudible] is sort of the principal wire-tapping statute governing the interception of e-mail communications. There are a variety of exceptions to the [inaudible] that are of interest here; the principal one is the right of access, under certain circumstances, for the service provider to intercept and view e-mail message contents, although they cannot necessarily be disclosed.

Depending upon the kind of e-mail system you're using, you're going to experience varying levels of security. If you're using a modem-to-modem link or an in-house system, the security is really under your control. My understanding, from a very non-technical standpoint, is that these things can be made quite secure, and probably provide the most secure method of communication.

The next most secure would be a third-party provider like an MCI Mail, a CompuServe, or an America Online. The issues that arise there have to do with really with the [inaudible]. Under the [inaudible] a provider like an America Online technically has the right to view, although not necessarily disclose, stored e-mail — which means e-mail waiting in your mailbox to be delivered. They also have a “carve-out” where there's consent of either the recipient or the sender. If you're going to be using e-mail for this kind of confidential information, it's

probably worthwhile to look at your provider agreement and see whether somewhere buried in there you've consented to them reviewing your e-mail for any purpose. Depending upon the sensitivity of the information that you're sending, you might want to know whether the person that you're sending it to has a similar consent built into their agreement with their provider. Most of the reputable providers don't go around reading people's e-mail, but it's a possibility.

I touched on both of the issues with the third-party provider, so the third option is the Internet. The Internet obviously provides the lowest level of security. This is because your e-mail message may be routed through any number of computers; it's not going over proprietary network. Nobody's going to be able to tell you in advance whose computer it's going to bounce off of; people along the way could intercept the message if they wanted to, although they may be prohibited by the provider from doing it. These kinds of things are very hard to detect, and it's not at all clear how much passive interception of e-mail goes on out there. If you're sending highly proprietary information out over the Net, you might want to be concerned about that. Also, the [inaudible] does not prohibit inadvertent interceptions as it's going through some one of these routing systems along the way, and if somebody inadvertently intercepts it they wouldn't be prohibited from viewing its contents.

In final, the [inaudible] does not apply outside the United States, so to the extent that you're communicating trade secrets and other things by e-mail to recipients who are located in foreign jurisdictions, you may not have any kind of wire-tapping statute coverage. You really have to look into the jurisdictions through which your message is passing. I think those are the two principal concerns that people may not be aware of.

Other concerns are the ones you see listed here. The first is the possibility that e-mail is used for sexual harassment. Obviously, it's not a unique communications medium. People can pick up the telephone, people can make casual remarks, but there are aspects of using e-mail which may get particularly susceptible to this kind of use. In one reported account, an employee was sent 6,700 harassing messages in a ten-day period via e-mail. Obviously, if the employee who's sending the messages had to walk by the desk and drop off a note every time they were sending a harassing message, it might have been noticed by co-workers or supervisors; but they weren't noticed while sitting at their desk doing that sort of thing.

Another is a fairly well-publicized case involving Chevron out on the West Coast. Apparently, a variety of people at Chevron received pornographic e-mail from another Chevron employee. Partially as a result of that and partially as a result of some other factors, they banded together and tried to bring a class action lawsuit against Chevron for sex discrimination or sexual harassment. Chevron settled that case for somewhere around \$2 million reportedly, so it can be a significant issue for businesses.

The second issue is employee postings using the company e-mail address. If you have Internet access or access to UseNet groups, you have to be concerned that if your employees are posting messages out there, and there is some indication on the message that it comes from the company, the people out there in the world are going to interpret that as an official statement of the company — and obviously, people want to be able to control the flow of so-called official information out of their organization.

A third concern is copyright violations. There's been a lot of discussion of that today. You obviously don't want your employees downloading, copying and distributing copyrighted materials in violation of the copyright laws across your e-mail system. You don't want to be caught in a situation where somebody argues that you somehow facilitated a violation of the copyright laws. That's really the same concern that system providers have, and the final concern is the theft of trade secrets.

There have been a few well publicized cases where employees have taken company trade secrets and e-mailed them surreptitiously to competitors. There is one involving Borland

that some of you may have heard of, where apparently an employee of Borland allegedly sent some trade secrets of Borland to Symantec two weeks or so before leaving Symantec for a permanent position. So you want to kind of keep control perhaps on this sort of thing.

What all this boils down to is that if you're going to use e-mail on any kind of enterprise-wide basis, you ought to have a policy on how you deal with e-mail. I don't think I'm going to get into the details of the policy. If you look at the written materials of the CD-ROM, you'll see a series of guidelines. You'll also see some sort of a much more extensive discussion of the kind of things that you want to think about in formulating a policy. But I do recommend that if you have an organization that is making extensive use of e-mail, that you have a policy. It's the only way really to protect you against various kinds of claims that I've talked about, and perhaps to prevent those types of claims. It's relatively painless, and I think that the article in there should be helpful in implementing that kind of a policy.

One of the issues that naturally flows out of the policy — and I'm not going to spend a lot of time on this either, although you'll see a discussion in there — is whether or not to monitor your user's e-mail.

It is an incredibly controversial topic in legal-political Internet circles all over. For me the issue is not really whether or not you do it — because I think you have to make that as a business judgment, an organizational judgment — but you should be aware that there are certain legal constraints on what you can and can't do. Those arrived primarily under [inaudible], although they may arise under state law. If you look at the written materials, you'll see an extensive discussion of that.

With respect to the state laws, as Lance Rose talked about in the last presentation, there's a “blue sky” issue. State laws are going to vary from jurisdiction to jurisdiction, and you're really going to have to consult with somebody and kind of clear your e-mail policy on monitoring through all of those laws before you go about implementing it. But the bottom line is there are issues you should be aware of with e-mail. You should take care of it with a policy, and you ought to think about what you do with the policy, communicate it to your users, and stick to it.

For the last few minutes of the session, I'm just going to quickly run through some of the emerging issues and the emerging uses. This is not an exhaustive list, but it's an example of things that are going on, that people are thinking about.

The first one is jurisdiction. Where can I be sued and what law is applied? I wish I could give you answers to those questions, but it is very unsettled right now. I think that generally if you're doing these things, you're not going to be able to be sued in every state of the Union if you don't have a physical presence there, or by the simple fact that you have telepresence. But again, I think this is an evolving area, and nobody's really sure where this is going to come out.

Intellectual property rights; those are significant issues with respect to trademark and copyright. I would suggest to everybody if they've got any concerns in this area, they should consult people in that area.

Specifically, one of the issues that is coming up right now are the domain names; and a lot of these issues were touched on earlier today, and I'm not going to go through them again.

The content responsibility, again, has been touched on earlier today. If you are putting content on the Net, who's responsible, the provider or the systems operator? Again, there are decisions that go both ways on that, and it's far from being settled right now.

Some of the other emerging issues that are coming up are in gambling. Some people may have seen that you can now do gambling on the Net, either with fake money or with real money. I think that there's a variety of issues that; to me, it's fairly clear that it's illegal activity in many states of the Union, and the fact that you're doing it is probably going to be — it's probably violating some criminal statute.

Maybe the more interesting question is that there probably will be a jurisdiction — like the Cayman Islands, or some other jurisdiction — that will become the host to all these operations, and they will essentially be immune from any type of claim. And even if you were able to make a claim against them, I would suspect that because they're probably not monitored, and you think you were ripped off in some way, that on public policy grounds, because you were conducting an either illegal or socially inappropriate activity, that courts would not allow you to enforce that if you had somebody to enforce it against.

The next issue is tobacco and liquor advertising. There is an open question right now; some tobacco companies have put up Web sites or are contemplating putting up Web sites. There is an open issue as to whether or not FCC law, which prohibits them from advertising over the telephone system, is going to take jurisdiction over the Internet. They have not done so yet, but there's a possibility of that. Again, that will be fleshed out more.

“Cyberbanking,” and digital cash... The first Internet bank has opened up, and it is able to take deposits. It's going to be interesting to see how it does. The more important issues that you have in that area is with respect to digital cash, and the ability to evade taxing authorities. I think that that's really the principal concern. There's probably significant uses for either money-laundering or evading taxes, and there will be, I believe, a lot of issues there that will be fleshed out in the near future.

With respect to securities laws, you're seeing more and more purported scams that are going over the Internet. The activity is probably no different than what goes on in everyday life, it's just that the media is much more attracted to it because it has an Internet side to it. From a regulatory point of view the SEC has recently issued a ruling that provides that the terms and conditions under which the electronic delivery of a prospectus occurs is acceptable behavior. Again, the SEC is one of the agencies that's really sort of moving towards a paperless society, and they are adopting rules that would allow for that.

One of the big issues for anybody who's doing business on the Internet is collection of sales taxes. Right now the existing laws with respect to that are, if the analogy is going to be mail-order companies, that unless you have a physical presence you're not liable for collecting sales taxes on your transactions. I suspect that as the states and the federal government are scrambling for more and more revenue dollars, that those rulings are going to be revisited; and I don't know if it's going to be retroactive or not, but I will be very surprised if you don't see legislation in that area in the near future that is going to allow that to be picked up.

The last issue is FTC regulation. In April of this year, the FTC basically indicated that they had a task force started that was going to start investigating consumer fraud and other things going over the Internet. Again, I think it's just a movement towards more and more regulation on the Internet, something that many of you long-time on-line users are not going to be used to.

That's it for the formal part of our presentation. If anybody has any questions, I would be happy to take them.

M: [inaudible]

Wayne Martino: There's supposed to be a CD-ROM of the materials? Correct. They are supposed to be provided to all attendees, and that should have our materials on there. Yes.

M: [inaudible]

Wayne Martino: Absolutely. It's a very good question. The question is whether or not there are international aspects of jurisdiction — and I was not trying to suggest that it's just a U.S. issue,

because you can operate anywhere in the world. You're absolutely correct. There are very different laws with respect to First Amendment.

The First Amendment protection that U.S. citizens take for granted doesn't exist in any other countries, and similarly, with respect to copyright, the U.S. protections are going to be very different. You can also have circumstances — in the trademark area, for example — where you could have a company that has a trademark on the name “ McDonald's” in Belgium, and someone who has it in Italy, and someone who has it in the United States, and if they all are operating on the Net, who's going to have responsibility? There's no doubt that the international aspects of this are considerable, and I think that it'll probably be a long time before you're going to see treaties that are going to be adopted, if ever, that are going to take care of a lot of these issues. Yes.

M: [inaudible]

Wayne Martino: Sure, the e-mail address is w.martino@callnet.com. Anybody else? We have our last session of the day, which is going to begin at 4:15, on “ Structuring Strategic Transactions,” and we look forward to seeing you there. Thank you.

INTERNET LEGAL STRUCTURING STRATEGIC TRANSACTIONS

SPEAKERS

Wayne Martino, Esq., P.C.
Brenner, Saltzman & Wallman
Newton Brenner, Esq.
Brenner, Saltzman & Wallman

Wayne Martino: Why don't we get started? What we're talking about is the structuring of strategic transactions. My name is Wayne Martino. My partner Newton Brenner is here, and maybe we're a good example of a strategic relationship.

Generally, strategic relationships are between larger, established companies and smaller, emergent companies. They have a variety of names, from strategic alliances to corporate partnering, and probably what type of transaction it is is only limited by the names the parties can attach to it. As the definition shows, it is a collaborative relationship which helps each party leverage their existing resources to achieve a strategic business objective. Generally this involves the alignment of technological innovation, organizational resources, management expertise and entrepreneurial ability. Companies may enter into a number of strategic alliances. It is not limited to one. They may also do it with one product.

Today, you'll hear Newton or I refer to different companies in different circumstances where we have encountered strategic alliances. One that we'll refer to is a medical — a software company that has developed a computerized medical record, and we'll be talking about some strategic alliances that they could look at. Obviously, this is a hypothetical case.

Probably the most critical element here in choosing the strategic partner, and I can't emphasize this enough, is who the partner is going to be. And if you don't have a good partner and you haven't identified why you're entering into the relationship, why both parties are entering the relationship, the possibility of success or failure is clearly going to be magnified. And I think there are five areas that you should look at.

The first is the compatibility of the goals. Do you both expect — do you both want to go in the same direction? Do you both have mutual incentives? If it's a one-sided relationship, and if this is supposed to be collaborative, it probably is not going to work. Both parties have to get significant benefits out of it. Is there a mutual commitment? Do both parties want to do this? At what level of organization are they committed to doing this project? Are they doing this project simply because they think it's a good idea, or is it really part of their strategic plan? How responsive is the other side going to be? Again, this is very critical when you're dealing with large companies, in that you've got to make sure that you hopefully have a champion who's at a significant level on the other side who will devote potentially some career capital to make this happen.

Generally you're always going to have development problems that will be encountered, and you need to be able to deal with those quickly. And if people are not going to be able to deal with them quickly and they're going to delay them to the extent that there's technological innovation as part of that, you're probably going to lose it. And the last concept is longevity. How long is the project going to take? Do both parties expect it to occur at the same time?

Newton Brenner: Wayne, the one thing I just might add, which maybe overrides all of these, is realism. That is, you've got to be realistic in what you can contribute in terms of whether you're the big company or the small company. The other guy has to be realistic, too, because if you just undertake this as hubris and showmanship and exaggerate what you think you're able

to do, it will crash very quickly. These partners are meant to live together and you're really got to think through what you can commit to and also what the other guy can commit to.

Wayne Martino: The next area is, why do people get into it? What are the advantages? Well, the advantages to the established company are numerous ones. They can leverage their existing resources. There may be a circumstance where they have a great marketing and distribution facility, but they don't really have the products to put them in. For the small company, it could be the exact opposite; they may not have that. So the large company is probably trying to leverage a resource that they have to their advantage. They may be looking to expand or maintain their market presence.

Again, it may be a question of technological innovation. They may not have the products. They maybe want to fill out their product lines and reduce the risk of product obsolescence, so that they will consider entering into this relationship.

There is also the lower cost of development. Lower labor cost and lower overhead are the hallmark of small companies. They can do things on a much cheaper basis because a lot of them are working for subsistence level, because they hope that plays in the long-term equity and not on a dollar per dollar salary.

The next is the access to entrepreneurial acumen. Smaller companies are generally probably a better incubator for entrepreneurial activities, and larger companies will look to and hopefully get some cross-pollination with their existing workers. Also, I think that that's important because generally the smaller companies are not going to be sort of constrained by the views of the larger companies. Larger companies may have a methodology that they teach people — "This is the way that we do things," and do not necessarily want you to explore other ways. It may be helpful for them to see a different perspective.

The next item is the speed of technological innovation. Again, smaller companies may be closer to the marketplace than a larger company and you may need to do that. Combined with that is whether you want to keep this from your competitors or not, and that may be another reason to do this.

Additionally, there is the financial upside. What you'll see in these relationships more and more is an equity component. A few years ago, or more than a few years ago, the equity component wasn't always included in the deal. We'll be talking about that, because it's become a very significant element. Most of the larger companies are looking to participate in the success of the smaller company because they believe that they are contributing to it. Going along those same lines, in many circumstances they look at the transaction as a low risk acquisition candidate. This will give them an opportunity to do a sort of due — not legal diligence, but a business diligence that will allow them to really understand the company and the people and determine whether or not they want to make an acquisition. They can probably get it at a lower value because they already own a piece of it.

The advantages to the emerging company: I think the most critical one is validation. Aligning yourself with a larger company who's in the same industry or in a complimentary industry can be a validation of your technology or your product. It will carry you a long way to being able to raise money from additional investors, if that's one of your goals, and from venture capitalists, and from going public. What you will see with many emerging companies is that they will look for somebody to say, "This is good technology and we've bought it," because then they will be able to go to their customers and everybody else with that. And that is probably the critical element that you have to look at in terms of the benefits to the smaller company, because they will be able to leverage that substantially.

The second point is the ability to focus on their core capabilities. The smaller company may not be interested in focusing on product or distribution; they may simply want to be a

developer and they'll let somebody else do it. In the medical company that we mentioned as a hypothetical, for example, they may say, "Look, we just want to be a developer. We don't want to have a fully integrated operation, because what's critical to us is that we have an ability to quickly develop our product. If I've got to think about creating a fully integrated company, it's going to slow me down." So you might want to think about strategic relationships with somebody who, for example, might be a reseller or who could provide you with other benefits.

The next item is the access to experienced managers. This is probably both a positive and negative. Whether or not their experiences are good or bad, they've been through a lot of the things that the smaller company is going to face, and there is a significant benefit that you can derive from that.

The last two items are access to mature distribution channels and broad market exposure. Again, they may have an ability to get to markets that you can't get to because you're small, or because there may be a credibility issue. A larger company may have contacts that a smaller company just can't get to.

The last one is a lower-cost financing alternative. To the extent that the choices are between venture capital money or doing a strategic alliance, if you're getting the money from somebody who's doing a strategic alliance the primary focus of the large company is not usually on the financial side of it. So you're probably going to get a better valuation from them.

Newton Brenner: One of the things that you tend to see is almost a redefinition of corporate development. Many of the small companies never developed into an integrated business, but rather function as an R&D shop. It is likely that this hypothetical company that Wayne is talking about will never achieve its own marketing system. It may never achieve its own manufacturing system. What we see emerging in the very near future may be corporate development experts at companies that are going to be undertaking very little corporate development. At the same time [you will see] experts in the larger companies that are going to be used to fitting in and fulfilling those possibilities.

Wayne Martino: The next is the risk to the established company. One of the obvious ones is the market risk. Are they aligning themselves with the right people? If the program does not work out, are they going to be behind the development curve and not be able to do this product innovation themselves? There is obviously a financial risk to the extent that the project is not successful.

The risks to the emerging company can be substantial. One is the loss of independence. All of a sudden many of these emerging companies are — a lot of the individuals are expatriates from large companies because they didn't want to live in a corporate culture. All of a sudden they realized that to do this alliance, that there are certain concessions that they are going to have to make. Those concessions may be in where the product goes, because there may be a different financial or product agenda, a product development agenda that the large company has.

One of the things that you need to think about — and there are no really clear answers, but it's a situation that we've encountered numbers of times — is what happens if there is a loss of direction or focus, or a change in executive personnel in a large company? That is a very significant issue. It happens probably more often than not, where companies will get into projects and for some reason or another they will not want to continue them.

And the question is, how do you extricate yourself from that situation? Have you built in mechanisms to do that? It is a very, very troublesome area, and many people do not deal with it up front because it's so difficult to do, both politically as well as from an agreement point of view. But it is a very critical element.

The next item is the loss of an entrepreneurial or technological advantage. To the extent that the strategic relationship involves giving up part of the distribution or the marketing of the product, you're going to have some problems in that area with respect to how you are proceeding.

In addition, your technological advantage may be one of speed to the marketplace. You need to get there. To the extent that you've got a large company that has an organizational structure, it takes a long time to make decisions, in terms of not only going forward with a strategic alliance, but dealing with changes in development or things of that nature. If that results in delay and compromise, the innovation and the technological advantage that you had may be lost.

The next item is customer isolation. If you are giving the distribution to somebody else you may be removed from the customer. That may have been the genesis of your advantage when you got involved with the product, and you need to think about [the alliance] in that respect.

The next item is the risk of piracy, of proprietary confidential information or employees. Generally, you'll deal with this from a contractual point of view and you will have limitations on that. You will prohibit them from soliciting your employees; you'll have agreements that say that they can't use your technology. The important point here is not, "Do I have agreements there?" If it happens, what you've got to understand is that the large company is going to have much more significant resources than you, if you're a small company, to fight that type of behavior.

One of the situations I was involved with was a large company where they had taken the technology and put it in a subsidiary in a foreign country and were developing it there. Luckily, we found out about it and it ended up resulting in the termination of the relationship. But the prospect for my client of trying to enforce that, even if they were right, was going to be very expensive and very time-consuming. To the extent that you are dealing with technical innovation, you may lose your market advantage there and what you simply say is, "Look, I don't want to be in the business of litigation, I want to develop." But you've got to realize that's a significant risk.

And the last item is an unfavorable future evaluation. You may be selling the equity too cheap to the large company if they want to make an acquisition. You may fail to diversify your products because they want you to go in one development area and not to be fully integrated.

Newton Brenner: Wayne, I just want to emphasize again the point that you've made very strongly, which was that you've got to look at the people, at the time you're making this deal, as people who are sitting at the desk across from you; but you've also got to realize — and it's critically important that you realize — that you are making a deal with a file. In the course of the six months or eighteen months or two or three years that it takes to fulfill any of these development functions, there is a good chance that the leader on the other side may change. What he's committing to do for you, because he sat across the desk and promised you that their company was behind him, may not be in the file, may not be documented, may not be part of the agreement. Someone else may have taken over the chair, and the enterprise may have some new risks. The new guy running it may be able to write it off as being the prior guy's mistake. You've got tremendous issues of corporate politics that you've got to be aware of when you sit down and make one of these deals.

So make sure that you're working your deal out not only face-to-face, but also make sure that what you need to protect yourself has been appropriately documented and the file supports it.

Wayne Martino: Now that we've talked about the advantages and the disadvantages, let's talk about what the structuring variables are.

The most important thing is the objectives of the parties. In determining how the structure is going to be, you're going to look at a variety of different areas.

The first is going to be the strengths and weaknesses of the parties. That may be from the different perspectives of marketing, from distribution, from technological innovation, from manufacturing. What you want to do is to leverage. Each company should hopefully be leveraging their strong points and hiding their weak points.

The next issue is, what's the desired relationship? Again, if people are looking at this as the first step to an acquisition, the structure could be very different than if they are looking at it to say, "I need product or I need distribution and I'm going to move in that area."

The next item is the type of technology or product involved in this stage of development. There may be different relationships that are established depending on how close something is to the market, and that will result in different structures. The target market and the distribution method again will indicate to the parties what the type of relationship should be.

The ultimate ownership of the technology — again this is a structuring in terms of equity, whether it's going to be in a subsidiary in a joint venture — but who at the end of this process is going to own this technology? It's something that needs to be identified and to the extent that one party owns it, is the other party going to have some co-exploitation rights or some exclusive market opportunities that they may be able to exploit?

And the last item is the expected reward for a successful development. If this thing works as everybody hopes it's going to work, what are people going to get out of it? Is it going to be an equity play? Is it going to be just manufacturing? Is it going to be additional product development, additional relationships?

I've indicated four types of structures. There's obviously also different relationships that you can have in terms of the business relationship, but I think that they generally boil down into four, maybe five if you include distribution. Let me just quickly run through them.

The first is a joint venture relationship. That's an association where two companies will generally take products and capital and other facilities and put them into a new entity in which there will be joint ownership and control, and they will share in profits and losses.

The next type is a product development agreement. That is an agreement where one party will generally fund the development of a product for their use or for some co-exploitation for some period of time. The funding in this area is usually based on the satisfaction of milestones.

The next area is technology exchanges. The companies may have complementary technologies, an "I'll give you yours if you'll give me mine" type of relationship, and that can be the basis for a successful relationship.

The last one is listed as licensing, the granting of authority to use or exploit some core technology or product. Again, this may involve co-exploitation rights or some defined market opportunities in which the licensing can occur.

The next item is equity participation structures and again, there's lots of variations on this. I've just identified four of them that generally come up. The first is common stock or common equity, where there's a straight percentage in ownership and sharing in profits and loss and success and failure.

The next is preferred stock or preferred relationship. When I'm talking about stock or equity — and we'll talk about this more later in terms of structures — I'm not suggesting to you that it has to be in a corporate structure. There may be partnership structures that you might want to consider, and we'll be getting into those. But the preferred relationship would

generally involve some preferential return of capital or payment of dividends before the non-funding company received any distributions. Incorporated with that may be some conversion into some common stock or common equity so that they can participate in the equity growth of the company.

The next item is a convertible security. It can take a lot of forms. Generally, this is a security that's going to be convertible into equity in one form or another. It can be in the form of notes or convertible debentures, things of that nature.

The last items are warrants and options. These are rights to participate in the equity growth through a right to acquire stock or an equity interest at some period in time. It may be at favorable prices, it may be at today's market price. It may be at a market price that is higher than today's, but it's not a direct equity investment. It's a mechanism that many companies will use so that they have the right to tie into a valuation on a company today, but they are not going to take some of the risks from a financial statement point of view that are associated with having an interest today.

The next items that I'll quickly run through are some alternatives to equity participation. For owners of small companies, absolutely the last thing they want to do is to give up [inaudible]. They will fight and claw to limit the points. They will look for as many different ways and as many different structures as they can to try not to give up equities. I've listed a few here. Generally, to the extent that they need funding, you can look for advanced payments, large up-front payments that are going to fund development for some period of time or that will allow them to exploit some market opportunity. Again, this is an alternative to a equity component.

There may be R&D funding. They may say, "You fund the development of this. We'll pay them on a monthly or on a quarterly basis based on budget and based on establishment of milestones instead of you taking equity." You may ask for loans from the large company. You may look for guarantees to third parties for either provision of loans or the provision of facilities. And again, I think that sometimes large companies are receptive to these types of structures. You may look for favorable leasing terms for facilities that may otherwise be dormant, or on equipment. There's a possibility that you can get personnel loaned to you.

There are some complicated issues here in terms of whose employee the individual is at the end. What type of relationship do you have regarding confidential information and proprietary information? But they may have employees that are either excess or that are dedicated to certain projects that they may want to provide.

Another area in which they can help is to do a market research study for you. Again, these are "off the balance sheet" items that they may be able to do. The last is to be a beta site which they are probably very interested in, if it's in the software area, so that they know how the product development is going.

Newton Brenner: Wayne, sometimes the list that you've given for the alternatives may be preliminary, and gives both the small company and large company a way to get started.

At the early stages the nature of development may be so indefinite that they can't really put a price on it that would be fair to either party on any equity participation. But we've seen all of these techniques that Wayne talked about operate. Many of the large companies are familiar with them and are able to function with some of these without demanding equity participation in every deal from the inception.

Wayne Martino: The next item that we're going to focus on is, what are the major issues? What things do you see that come up all the time that need to be defined in the agreements or in the relationship? And this is not exhaustive; again, this is just a checklist of the things that you

should start thinking about as you're thinking about whether you want to enter into a relationship and what it will mean.

The first one is critical. They're all critical, but the first one, the rise to technology, is something that you need to very clearly delineate: the ownership and licensing rights to the core technology as well as to the enhanced or improved products. Part of that also will generally include an affirmation of the technology owner's rights to use it in unrelated activities outside of this venture. I can't stress upon you the importance of that enough. You don't want to contribute the technology and then say, "Oh, by the way, I've got another development project and we use it in both projects," and then you've got to go back to your partner and ask them to allow you to do that. Those are issues that you've got to identify early.

One of the other items with respect to the rise in technology is that you have to identify to what extent these technologies or practices incorporate existing technology and create issues regarding ownership. To the extent that you identify who owns the product and what rights they have, you've got to make sure that you clearly — if licenses are needed for the product that were ultimately developed from the company that has a portion of the technology that was used as the base, you need to have that.

With respect to technology, one of the things you'll also consider is any limitations on the right to work with competitors and whether or not there is going to be any post-development collaboration.

The next item is proprietary and confidential information. As I indicated earlier, generally you're going to incorporate covenants that are going to prohibit the use or disclosure of confidential information. In general you may have covenants that restrict certain activities or solicitation of employees. Those are things that you should identify early as to whether or not they are relevant. You want to make sure that the technology is well-protected, because for small companies that may be all that they have.

And you should also realize as you enter into this development program that the large company is probably going to require all of the key employees and officers from the small company to enter into nondisclosure agreements, and assignment of invention agreements. To the extent that you don't have that now, if you're a small company, it is in your interest to do that for a lot of different reasons, the most important of which is to make sure that your ownership of the technology is very clear. You don't want to end up in a situation where an employee says that they had developed this [at some point that was] not during working hours, and that you don't own it. Among other things, that can result in a delay, if there's any questions as to ownership, as to whether a company wants to get involved or not. Generally they're looking for as clean a relationship as they can, and if you're trying to sell technology and if your ownership rights are at all in question, you need to deal with that early and get it resolved.

Newton Brenner: Wayne, I think the next topics that you wanted to discuss were the major issues. In fact, Wayne, let me give you these.

Wayne Martino: All right. The next item that we'll talk about is decision-making and control. Who's going to be in day-to-day to control of the operation? To the extent that there's cross-ownership, there can be issues of day-to-day control. That generally is not the circumstance, except in joint ventures where both parties may contribute employees. You more likely will see this situation in terms of whether there are going to be rights to override decisions, unless there's unanimous decision-making with respect to certain issues as to whether or not certain deals can be done, whether it's a sale of the company, a sale of the technology or a deal with the competitor. One of the features that you will see that is used, a mechanism that's used to

do this, is generally going to be classes of stock that will allow different voting on certain matters and may allow different people to have rights to elect to the Board of Directors.

The next item that Newt and I both talked about before is what happens in changes of direction of the companies. I indicated to you that it's a very touchy area, because nobody really wants to think about it. But one of the things you need to focus on is whether or not that's a possibility, so you can create any mechanisms that will deal with that.

And I'll tell you up front that it's not easy to do, but in certain circumstances you can do it because you may need to deal with stalemates and changes in strategic direction or policies. One of the items that you may consider, if things are done at the Board of Directors level, is to have less than unanimous decision-making at the Board level.

Say, for example, that you've got six people that have to make the decision at the Board level. If it's less than unanimous — let's say that you have to have four or that you have to have five, on the theory that you've got to have at least two of the people from the other side agree to a development program — there is some possibility that you can get it. Generally, you're going to see people move in lock-step on a company basis. The one benefit that you have — and I can't tell you that it's really substantial, but I've seen it used — is to impress upon people at the Director's level that they have a fiduciary duty to the company, not necessarily to their employer. Because they're directors they have a duty of loyalty to this company, and they should not be making decisions that may not be in the economic or business interest of their company or may not be in the best interest of the company that they serve on the Board of.

The next item is the use of milestones. Milestones are — and I think Newton mentioned this before — critical. When you establish those, what it is going to do is to focus the parties on the specific goals and tasks to be accomplished, and hopefully it's going to introduce some realistic expectations in the process. One of the things you'll find out as you start the process is that certain claims may be made, certain ideas will be bandied around about where the development of this is going to go, how long is it going to take, and what we are going to do.

As you move from that stage to actually trying to document and establish what the milestones are — and these milestones may be important because they may trigger funding or they may trigger certain transfers of ownership — the parties may change considerably in what they've said in the beginning and what they're actually going to commit to. And that is a critical element because, especially with large companies, you are probably going to be analyzed against how you perform to this plan. To the extent that you don't have a realistic plan from the beginning, the relationship is probably off to a rocky start.

Also, the other thing that the milestones will allow you to do is that sometimes they will allow you, to the extent that they have not been established, to get out of a relationship before there's either a complete loss of a financial investment or a complete loss of a market opportunity.

The next item that we have is market exploitation. And generally, here I think you've got to strike a balance between the large company's objective of getting as great a share of the marketing opportunity and the marketing rights as they can with a smaller company's desire to carve out areas of permitted activity in order to maximize their market penetration. One of the major issues that you'll see here is exclusivity.

Exclusivity can be defined in a lot of different ways, from geographical territory to field of use to product linkage. It is an area in which people need to be particularly sensitive, because to the extent that they are being excluded from market opportunities they need to realize that if they've given up an exclusive, they're not going to be able to go back into that area at a later time.

The next item is manufacturing rights. In certain circumstances you may get into a situation where the manufacturing rights for the product may not be available or that the

manufacturing rights will be what the company has at the end of a development cycle. They've licensed all of the product out, but they can still build a successful model based upon their ability to retain the manufacturing rights.

The next item that we're going to go to are the equity investment issues, and they are not insubstantial. Newton, I'm sure, will liberally help along in this one.

The first one is the type of participation that you're going to have. We touched on that a little bit before in terms of whether it's going to be a common relationship or whether it's going to be a preferred relationship, or exactly what that relationship is going to be.

Newton Brenner: While there are many definitions of how you're going to structure the deal in terms of common or preferred stock, the thing I think that you'll find is most common and most fought about are the items at the end of Wayne's list.

Today, it's not a question of whether I bought common stock or I bought preferred stock; the question is, how do I get out? When do I get out? What's the term? Is there a way that I know I'm going to get my money back, or a shot at getting my money back, in three years or five years or seven years? But whether that's done because I've got the right to cause the company to go public, or cause the company to redeem my stock or cause the company to put itself on the market — those are issues that create tremendous pressure in factoring out all of the elements in the equity relationship.

The anti-dilution elements relate to [the fact that] I'm putting money in. I value the company at \$10 million even though all I've seen was a business plan and a couple of pieces of software; but if I put in \$2 million, for 20% interest in a \$10 million company, if six months from now things haven't gone in the right direction and someone puts in a million dollars for another 20%, I want the right to change my deal. I want my \$2 million to be recast into the same money structure that the new guy did. This can create tremendous friction in negotiating the relationship; but generally, if you're only redefining the relationship with anti-dilution provisions because you didn't perform in accordance with plan, you'd better be prepared from a small company point of view to face that possibility.

Wayne Martino: The next item is [inaudible] calls and redemption rights. [inaudible] and calls are obligations to either purchase or sell securities. Again, if one of the critical issues is what's the exit path for the large company making the investment, they may ask for a right to require a purchase or require a sale of their securities. There may also be, from a small company's perspective, a right to redeem the large company's shares at some point if the relationship is either going very well or very poorly. There may be opportunities to recast or take out equity partners so that the development in the companies can move forward.

The next is the tax implications, and it's really Newton's area and he'll guide us through this area.

Newton Brenner: There are a couple of points that are worth mentioning in the tax area, even though there is no question that this area of tax and accounting does not drive the structures that are put together in the corporate partnering — we've got to make it a business deal that works first.

Under the tax caption, you should understand that most of these deals in some respect recognize a significant amount of wealth in technology that is in its nascent stage. The question comes when the large company says, "We want to do this not as a loan or not as a beta site test, but we want to organize a new company with you. You put in this technology, we will put in X million dollars. The effect of the new arrangement will be that we recognize what you've done is already worth \$10 million in terms of our evaluation, but it only cost you \$500,000 to

get there.” Do you have a problem in realizing that you have a major gain just because you transfer your technology to a new entity with a financing corporate partner?

The answer is, you can do it. You can transfer technology either to a new corporation or to a new partnership without recognizing that gain, but you must be careful in doing that. There are some old revenue procedures that say the only way to do it is that you’ve got to transfer all the technology, all the elements of the invention to the new deal in order to do it tax free. That is generally not followed today. There are some private rulings, and some other materials in the world of tax law, that says you can transfer significantly less than all of the technology to a new entity and still not have to pay any gain measured by the value of the technology at the time of transfer. When you’re doing one of these new structures with a capital partner you’re going to go through issues about what kind of structure to choose.

Tax people think in terms of pass-through entities and non-pass-through entities. Pass-through entities are limited partnerships, L.L.C.s, taxes, partnerships. What they mean, generally, is that there is no separate level of tax at the entity structure. If we own this structure in a 40-60 relationship, 60% of the elements go to the 60% owner, 40% go to the 40% owner, and there’s no tax paid at the entity level.

On the other side we have a typical “C” corporation, which is a tax-paying corporation that can be owned in various ways, with common stock and preferred stock by two partner groups, or more than two groups if you have more than two participants. The entity will pay tax itself separately.

The advantage of the corporate structure is that it fits what’s called “reorganization” models. That is, if one of our favorite large corporations comes along and offers stock for this company that we’ve put together, we can take the stock in the large company on a tax-free basis. There are just a couple of things from a financial statement point of view that I want to mention to you.

Most small companies don’t have the resources and don’t have the inclination from day one to start with audited statements. If you eventually want to sell your company for stock or for cash to a company that’s a registered company on the New York Stock Exchange or on one of the other exchanges, as long as they’re registered with the SEC, there are limits on the ability of those companies to acquire your company if you do not have audited financial statements. Those limits are complicated, and they relate to size. Generally they come up when you are adding something like a 10% increment in either sales or asset size to the company that is acquiring you. If inventory is not a major factor in the operation of your business — and in many of the small companies that we see, inventory is not — you can get statements audited after the fact. But you may very well need them.

Wayne, I thought we just might talk a little about this [hypothetical] software company because I think there are some interesting hypothetical issues that may illustrate the problems at hand here. Then we’ll take some questions.

Wayne Martino: I’ll give you examples of strategic alliances that this company might consider. One of the strategic alliances may be with a hardware manufacturer. They may be going into hospitals or doctor’s offices. It may be a non-mainframe technology, maybe a PC technology that those facilities don’t have, and they may enter into a relationship where they will align themselves with a large manufacturer who will provide discounted price and will in some way resell their product for them.

They could also consider an alliance with a service provider. One of the things that this company may do is to have a medical record and, for example, let’s say that they create a host server with a large communications company that is going to be the one that maintains all of their information with respect to their customers. That company is going to be the one that’s

going to be serving it out to the same industry that may, for example, have a competitive product of theirs. But that company may have decided that this product is better and they want to add it to their repertoire of products that they have. They could consider a licensing agreement, a reselling agreement or some other relationship with them.

From a collaborative point of view, there may be companies that have certain applications that this company does not have, and it may make sense to be able to sell a whole suite of products. They may enter into different relationships with somebody that has, for example, an application. There may be a billing application; they may have a medical application, for example, that provides for recording of EKGs or provides for a recording of x-rays. They may consider doing a relationship with a company that may be doing this service so that they can provide — in addition to doing the servicing and in addition to doing the developing, they can service the product also. There are a host of different relationships that they can consider.

Before we take the questions, I'll leave you with a few thoughts about successful relationships. The relationship doesn't end once the paper, to the extent there is paper involved, has been signed.

There are a couple of things that people should think about in terms of maintaining a successful relationship. Maybe the most important is always selling the strategic logic of the relationship. We encounter this very often, the fact that parties change and you need to make sure that you have committed people on the other side. To a large extent that's going to result in continuing selling what the relationship is.

For a large company, it generally is not going to be that critical to them that the relationship be successful. To a small company it may be all that they have.

The second item is perform the plan. If you've committed to doing something, and again, you should think about this early, you better perform to plan afterwards, because that's the way that you're probably going to be evaluated.

And the last is communication. You've got to communicate with the people on the other side. To the extent that you have problems that you anticipate, an early warning on those is probably the better course of action, better than seeing if you can fix them or seeing whether or not the other side is going to be concerned about it. To the extent that people believe that you are not communicating with them and you are not telling the whole story, it can destroy the relationship of trust that is critical to this going forward.

We'll now turn it over to anybody if they have any questions. Yes.

M: [inaudible]

Wayne Martino: The question is, in the next twelve to eighteen months, what deals are going to happen in the Internet? I think that you can look to see what's happened already. You're looking at the on-line service providers entering into relationships with browser companies for browsers. You're seeing relationships between content providers; a good example of that is that some of the content providers that provided material to the on-line services like America Online or CompuServe are terminating those relationships and either putting up their own Web page or going to a new service because it's becoming available.

I think that you're going to see a lot of transactions like what Netscape has gone through, where they're going out and buying up complimentary applications so that they can broaden their market exposure. You know, it's interesting that Netscape started from nothing and is now the eighty pound gorilla in the industry.

I think that another possible relationship is, to the extent that their games are going to go on to the Internet, you may see relationships between having a game on the Internet and at the same time having a relationship with a manufacturer like Sega or Nintendo to do a non-

Internet game. And I think the industry is growing so much that you can probably go and look on any given day and see a new strategic relationship that's going to be established.

Yes, over here.

M: [inaudible]

Wayne Martino: Yes, well, in terms of being at risk — the question is, in the limitation on future valuations for the company, what does that really mean as to being a risk? To the extent that the strategic direction of the company is being dictated by the large company, they may have a different motivation as to how successful they want you to be and when they want you to be successful.

If they've acquired an equity interest with an idea that they are eventually going to acquire you, their motivation may be to bring the product to a development where they know that it's going to work and then make an acquisition of the company. What that may mean is that they may restrict you from doing deals with competitors, that you possibly could be limited not necessarily contractually, but just on where your focus is in terms of what other market opportunities you can exploit.

Small companies generally have very limited resources, and if you are spending your time trying to meet the expectations or perform to a plan with a large company, that may limit what the company does in other spheres and therefore decrease the value.

Newton Brenner: Yes, you're making a fundamental choice when you pick this partner. You're making an extremely fundamental choice, maybe as important as who the chief executive officer of the company is or who the chief technical officer of the company is. And I think what we're trying to say is you should be cognizant of that choice and the importance of that choice, in that it could radically affect the future valuation of the company.

M: [inaudible]

Wayne Martino: The question is, what are the legal risks of the large company with respect to dealing with a small company, from a marketing point of view and from a confidential information point of view? I think your concerns probably are a couple. First, the access to confidential and proprietary information, to the extent that that information is available to you; you may exploit it in other areas, and how are you going to deal with that? From the large company's perspective, are Chinese walls going to be created and are they going to be honored?

The other issue, I think, that is inherent in your question is to the extent that you're on the Board of Directors, and the question I raised before in terms of the duty of loyalty and the exploitation of market opportunities. You may have an obligation to refer those market exploitations to the small company because you are a Director, or you have some fiduciary relationship that has been created by virtue of having the relationship with a small company.

Newton Brenner: Some of the confusion that emerges when you're dealing with a company that — your company may have twenty or thirty or fifty employees. You could be dealing with a company with 25,000 employees on the large side.

We had a situation in which the technology that we were trying to make a corporate partnership with was an offshoot of circuit board technology. It turned out that we were delayed for weeks because the large company had a division that was 2,000 miles away, and in that division they had certain technical ways of dealing with photo finishings. And the photo

finishing compounds somehow were within — we thought they were pretty far apart. They thought that they were close and they couldn't tell us whether they were or were not close. We were paralyzed until it got straightened out that this could be done without violating the proprietary and other elements that they have in their photo finishing division.

Wayne Martino: Any other questions?

M: [inaudible]

Wayne Martino: Well, there are some industry publications that I think that you can look at in terms of what's going on. Without giving too much of a plug to Mecklermedia, if you look at the Meckler Web site, you will find there is a site called... I'm trying to remember the name. If you go into their Home Page, you're going to find a site that's devoted exclusively to Internet information and Internet business deals that are going on. And if you click through that and if you click through the last two to three months of postings to that area, you will find a lot of information about the deals that are going on.

And I think that is very helpful to you not only to understand what is going on in the industry, but also to think about it from a different perspective. Look to see what other people are doing. You may not want to do the same thing, but it may trigger in your mind a relationship that may be able to be established. It may not only do that, it may provide you with the names of people, because they may be included in the news stories of people that are active in the industry. Maybe they're venture capital people, maybe they're business development people.

If you're looking for large companies to establish relationships with, many large companies have business development units. Their sole role is to go out and look for strategic relationships and strategic acquisitions. And if you can find a list of resources of those through newspaper articles or through surfing around in different Web sites, I think that that would be a good place to start.

Yes?

M: My company recently was recently acquired. I was director of the company, and still am, and I [inaudible].

Wayne Martino: Are you still an employee?

M: Yes.

Wayne Martino: Well, the question is, to the extent that you are entering into a relationship or a relationship has already been established, what ownership are you going to have in things that you may have developed, and [the things] you may develop in the future? The absence of an agreement doesn't mean that whatever you owned or whatever was developed is not owned by the company.

What the agreement does is clarify that issue so that there's no confusion over ownership rights. To the extent that what you have developed, clear is the right word; but if it is within the scope of your employment, then the likelihood is that you have developed it while you were working for them and therefore they own it. To the extent that you believe that there are certain opportunities... What a lot of people will do is market opportunities that may be outside of the scope of their employment. They may do them in the evening, they may do other things. You need to clearly identify that.

The best way to do that is to have an agreement with them. You may not want to do that for political reasons, because it may not look good that you're doing something on the side. They may want to exploit it. They may not want you to spend your time doing that.

The other way that you can do it is to document when you did it, what you did and clearly identify it so that you have a track record that you can rely upon in the future. Because you've got to understand that what's important is not only what their rights are and what your rights are; if you're going to go and try to exploit this somewhere else, either through a new company or through a new relationship, the same type of issues that were created with respect to the ownership are going to be the same issues that you're going to face. Whoever you're going to enter into a relationship with may say, "I don't know that he clearly owns this technology." If there's a question, they may say, "I'm not sure that I want to exploit this opportunity until you get that cleaned up."

OK. I'd like to thank everybody for coming. That's the end of the day and have a good time at the show. Thanks.

WORLDWIDE WEB ESTABLISHING A WEB SITE : BUILD, BUY OR LEASE

SPEAKER

Matthew Cutler

Director of Business Development, net.Genesis Corporation

Matthew Cutler: . . . for network access, your available bandwidth options range all the way from 14.4KB per second over a simple dial-up line on a modem to 45 megabits per second over a T-3, which is generally overkill.

For a commercial Web site, the minimum/maximum need is a continuous connect. You need a Web site to be available all the time; having it over some sort of intermittent connection won't do when people are connecting from all around the world. Also, pretty much a minimum is 56KB. Generally the minimum these days is even probably less than that. It will rarely suffice as an introductory step; you can get 56KB out of an ISDN connection today, frame relay, etcetera. But these days more and more companies are moving towards a preferred T-1 connection and that's a bandwidth with 1.54MBs.

T-1s are very expensive, unfortunately, and there's a couple of options that you can exploit to help ease that cost. One is a fractional T-1, where you actually get a full T-1 installed, but you only use it in increments. You start out at 128K, and then as you need more bandwidth, if you need to go to 256K, your Internet service provider can flip a switch and you're ready to go.

What's also even more attractive than that is a burstable T-1, and for that at any one time you need to have full T-1 access, but it's metered. So if you, on average over a month, use 256K of your full T-1, then that's all you pay for. Providers of the burstable T-1 are Advantis or UseNet, and many of the others are beginning to provide that service as well. It's technically a little bit more complicated, but is very cost-effective and very high-performing.

For Internet service providers, you can choose them on a number of different criteria, like provider reach. There are national and even international Internet service providers, such as NETCOM; regional ones like NearNet, provided by BBN; or local such as [inaudible] over in Walton. Incidentally, all three of these are here at the trade show floor, so you can go over and pick their brains if you feel that's necessary.

They vary quite widely in terms of pricing; not only how much they cost, but their pricing structure — how they're going to charge you and what they're going to charge you for install. It's oftentimes very, very difficult to compare apples to oranges because they don't line up one-to-one. It's not like buying a pack of cigarettes where you can just figure out this one's \$2.19, and this one's \$3.00 — I know which one's cheaper. It's unfortunately not that easy.

They also vary quite widely in terms of service, not only in how well they respond in terms of customer service but how often their network goes down and how long it goes down for. NearNet, through BBN, is one of the top-performing Internet service providers in the country. When their network goes down — and all networks do go down — it's usually measured on the order of seconds or minutes, whereas with some other very large national service providers whole sections of the country could be out for days. And it helps to know their track record, to talk to people who have used their services and see what they have to say.

They also vary quite widely in terms of performance, to many people's surprise. When you talk about a T-1 — I threw the term "T-1" out before — you sort of throw it around like a commodity. A T-1's a T-1, right? Well no, not really, unfortunately. There is much more to know and much more going on that determines how fast your Internet connection will be.

The first one is available bandwidth. Oftentimes, with some of the smaller service

providers, what they'll do is they'll resell T-1 access off of a T-1, so they'll have a big pipe coming in and then multiple same-size pipes going out of that one node. So you can see that that's a very real bottleneck. At peak traffic times, there's not going to be enough bandwidth for everyone to use, and your actual available bandwidth will be much lower.

It helps to know a little bit about their network; probably the most important fact is latency, and it's best illustrated by the classic hacker 747 example. Latency is a measure of how long it takes your information to get from point A to point B. Now, when you're talking about T-1 and talking about bandwidth, that's how much information you can fit in the pipe. It's sort of a measure of fullness, I guess. But that's only how much information; it's equally important [to know] how fast that information can travel through the pipe.

The example 747 is: you can take a 747 from Logan Airport — whichever direction it is from here — stuff it full of magnetic tape backup tapes, about eight gigabytes on a little thing this big, and fly that from Boston to L.A. Now, you've just moved an incredible amount of information on these magnetic tapes, all the way across the country. The bandwidth of this 747 is huge, terabytes upon terabytes; however, to get one piece of information from a computer here onto that plane to L.A. and onto a computer over there, it takes forever. Even with a bandwidth that's huge, the latency is very, very long, so it's not an effective means of data transport.

It's important to understand what latency means because, of course, Internet service providers vary quite widely in terms of their latency statistics. Over at one Internet service provider that we were doing some consulting from several years ago, it took as long for information to get from our office to about 40 miles away — full T-1 and back — as it did to get to South Africa and back, over two trans-ocean links. So it can count.

We also have the issue of packet loss. Packet loss on the Internet works in terms of discrete chunks of information, individual packets that the information gets sent out on. And every now and then, due to a number of reasons, the packets will just get dropped. The protocol can handle that; they get resent, etcetera. But if you're seeing lots of packet loss, a lot of the information that you're sending out is not getting to where it's [supposed to be] going.

That same Internet provider that I just mentioned would experience extended periods of 30% packet loss. That's three out of ten packets getting dropped on the floor, and that's 30% off your T-1 right from the get-go. So these things start adding up.

And then finally, [there is] routing. The way the Internet works is that computers can route the information very effectively. You obviously want the fewest number of hops as possible. If I'm going from my computer here to the computers in the trade show, I don't want to be going through mainland China in order to do it. It's technically feasible, and may be desirable in very specific situations, but in general you want as efficient means of data transport as possible. In general, the routing figures for most providers are pretty consistent and pretty well-performing, but it pays to ask about that. When it comes to routing, if you're going through a company like IBM, where they have their National Backbone, you can send your data out but it will make two hops, get on their T-3 backbone and make two more hops. [It can] be all the way across the country in maybe four more hops, and then make two more hops and get to its destinations. So that can speed your data access as well.

Moving on to most computer hardware.... First of all, [are there] any questions about ISPs? I realize I'm going very, very quickly.

M: [inaudible]

Matthew Cutler: Sorry for the delay.

M: [inaudible]

Matthew Cutler: The question was, "Do all providers publish these numbers?" Unfortunately, no. Providers, in general, would like to have you think that a T-I's a T-I and that it all comes down to pricing, etcetera. The better ones like [inaudible] won't do that, but some of the other ones certainly will. That's why it's important to understand some of those issues so that you can ask the tough questions; and when you hear these things get thrown out, you know a little bit about what they mean.

What is worthwhile and what we've been working on for a little while — it's just a matter of getting time to do it — is to publish a paper that explains these in layman's terms and also do some data-gathering on the Internet. We have some technology that can do that, that can publish BBN's routing statistics over the past six months so you could go to a site and do that. To the best of my knowledge, it does not exist right now.

M: [inaudible]

Matthew Cutler: The question was, "Will I include some of these pointers at the end?" What I'll do is provide these slides on our Web site a little bit after the end of the show so that you guys can get to it there. But [it's] too much content to go through. I have lots of nuggets like that.

M: [inaudible]

Matthew Cutler: The question is, "Is this presentation presupposing that the Web site will be internal, located on a corporation site as opposed to external on an ISP site?" [We're] in the build section of the talk right now, all the issues are building, buying, etc., but what you can often do is buy our own Web server, build it up, and then just locate it someplace else, even though you own the physical box. So it's a little bit of a combination of both. It's worthwhile to understand.

M: [inaudible]

Matthew Cutler: The question was, "Are there reliable service providers in Southern Africa?" To the best of my knowledge, absolutely not, but that is not very extensive knowledge. I do know that for a long time there was a single Internet host on all of the continent of Africa, and it was served by a 96KB per second dial-in line. So Africa was not very well connected, unfortunately.

M: [inaudible]

Matthew Cutler: No, I'm not sure. The best place, in general, if you're looking for more information on a question like that is to look on-line; to go on the Web and see what you can find out. I know there are a lot of resources on Africa and Africa's Internet connection out there. Sorry.

Moving right along to the host computer hardware, this is the physical computer which actually stores your information, serves your Web requests, and will be connected to the Internet. Virtually every platform has Web service available for Macintosh, UNIX, Windows, Windows NT, Windows 95 — so you can publish off just about anything. However, different platforms will provide different degrees of access and different degrees of suitability for doing your Web server.

One issue which is becoming less and less of an issue today is software availability. For a long time all the key Internet software would first be published for UNIX, then for Windows, then for Macintosh — mainly because most of this technology was originally created on UNIX machines. But due to the market forces in play right now, you'll see a lot of new technology that's only available for Windows NT or simultaneous releases, etcetera. [Inaudible] is a company that supports both UNIX and Windows NT for the following reason of stability: it's very, very important to have your Web server available all the time, but if your hardware platform isn't stable and is crashing...

I'm running Windows 95 right here, which I have lots of horror stories to tell about. If your fundamental operating system or hardware platform isn't stable and is going to fall over very regularly, obviously you won't be able to serve your Web requests, so you need a stable operating system. Today that means Windows NT and UNIX. Windows NT is becoming more and more popular as a Web server, but it's yet to be proven in my experience as a very high-load, high-traffic, highly-secure server platform. Due to its current growth, though, I expect that to be established relatively soon.

The issue of performance. Interestingly enough, Web servers generally are not very processor-intensive. So if you get a Pentium system, you know it's not necessarily going to translate into super, super fast response times from your Web server. If you're doing large database [inaudible] where you're doing a lot of processor-intensive stuff behind the Web server, then it can count. But the key factor for terms of hardware performance is going to be in physical memory. Every time you get a Web connection it occupies some RAM space, so the more memory you have the more simultaneous requests you can get going. In general, the bare minimum is 16 megabytes of memory, but really 32 is the baseline. Our [inaudible] right now is at 64. It can get pretty unhappy at peak load times as well, so we probably need to get more.

We also have the issue, a lot of times, of dedication, where you just invested in this great unit's workstation. So, can we use it for anything else? Well, of course, that depends — as with everything here — on one [thing], how much traffic you're getting. If your server is just getting hit a couple times a day, then yes, you have a lot of spare clock cycles around. It depends on the power of the Web server. A lot of it depends on what else you're going to be using it for. Running mission-critical applications or very, very sensitive applications on the same machine that your Web server is running on is probably not a good idea. So it's a mix of a few things going on there. But in general, if you don't have a lot of load on your Web server and you have some other processes which aren't too sensitive running there, that should be fine.

For your Web server software, this is what actually serves your user requests. It's a small program or large program, depending on which one you have, that takes the incoming requests and says, "Oh, okay, I know what language you're speaking. You want the following document. Yes, you have permission to get it." [Then it] grabs the document and sends it back out the door. Again, most platforms are supported. The key consideration here is performance. How fast can this Web server handle requests? And how stable is it? How stable is the program itself under high-loads? Oftentimes it's a trade-off between performance and stability in terms of system requirements.

You may have a Web server that's very, very fast, but each connection requires a lot of RAM. So in order to run this thing effectively, you need a more higher-end workstation to do it. Or it's very, very stable, but it's very, very slow. So there's a lot of companies out there that you can see on the trade show floor that will promise the best of both worlds. It's generally important to talk to other people who are using them. Go out on UseNet, that's a good forum; [inaudible] Infosystems, the World-Wide Web — there's a whole bunch of them underneath there where people will talk about their experiences with Web service.

Commercial servers. For a long time the only servers available were [inaudible], the two

main ones each with their pros and cons. Today there's another very popular public domain Web server called Apache, which is an update to the NCSA code. That's what we're currently using internally. There's a number of commercial servers out on the market right now, and there's probably at least a dozen that are being shown on the trade show floor today. Features of those include user authentication, the ability to do secure transactions — which has entirely its own set of issues there — as well as some information processing.

Some of them have interesting database times, etcetera. Provider examples of that include Netscape, of course, with their commerce and communication server; Open Market with their servers, which incidentally only run on UNIX; and O'Reilly's WebSite . Our products support Windows NT, so we do a lot of testing on Windows NT servers; and O'Reilly's WebSite Web server is by far the best-performing one that we've come across [inaudible] platform. So that's one to be aware of, and O'Reilly is here today.

Okay, any questions on hardware or server software?

M: [inaudible]

Matthew Cutler: Does O'Reilly offer secure transaction processing? Not to the best of my knowledge right now. You can bet for most of the major server providers that if they don't provide it today, they will be providing it very shortly. I encourage you to go out ask them those questions over there.

M: [inaudible]

Matthew Cutler: The question was, "What do we like about the O'Reilly software over Netscape?" For instance, the O'Reilly software is one of the very few which is on the NT platform which is fully CGI-compliant, but it handles [inaudible] the way it's supposed to be handled, as opposed to through some roundabout ways.

Incidentally, just a little bit of a history about that. For a long time there was only one Web server that was publicly available called EMWACS. EMWACS handled CGI improperly due to some of the internals of how NT works, and many of the commercial Web servers, what they did was buy the original EMWACS code and then build on top of that. So at their very foundation they had some problems there. And that's, for example, what many of the other providers did.

It appears that that's what Netscape did initially, and they're working to correct that. But what O'Reilly did was get one of the very fundamental Web developers, one of the original NCSA guys, to rewrite an NT Web server from scratch. It's very stable. It handles CGI very well, it's easy to install and it's \$495. It's cheap. That's why we like it. We're always happy when our customers are using O'Reilly's WebSite because it means much less problems for our technical support team.

Okay, moving on to security considerations. Security gets a lot of good press these days. It makes good press and is probably a little bit overblown. This is security in terms of your network, not secure transactions, which is an entirely different debate. In security considerations, degree of exposure is key. This is how much information you have on your network which is considered very, very valuable or very, very sensitive. For most companies that probably means a lot, so security is something to pay attention to. The key factor is going to be your network topology. It's sad, but true, but the analogy between Internet security and safe sex is pretty right-on in terms of abstinence being your surest way not to catch anything. So outside of not having a Web server, not being Internet connected, there are incremental steps you can take away from that.

The safest way is to have a DMZ or a firewall, where your Web server is physically disparate from your existing network — there is no connection there. So for people on your internal network to get to your external Web server, they have to go externally and come back in. That way it's separate and self-contained and doesn't have access to other parts of your network. Unfortunately, that's a little bit difficult to pull off sometimes and it may not be the most effective means of serving your information or for using your hardware resources. It also depends on your available applications.

The WorldWide Web represents certain security risks. FTP, the ability to download files, presents certain security risks. Telnet, where you can have people who are remotely Telnetting into your system, [also presents risks.] If people aren't very secure with their passwords, or they choose their passwords to be their user name in reverse or something very, very obvious, then people who can log in under a regular user's name are going to have full access. Finally, believe it or not, even running [inaudible] mail or mail packages will present certain security risks as well; small ones, but ones that are there.

In general, more than anything, it pays to know what you're doing when you're setting up your security solutions. You can have hardware and software solutions such as firewalls, but even the most secure firewall in the world will be very insecure if it's not set up correctly. So if you have people on staff who know what what's going on in the security and network side, keep them on staff and make sure that they pay attention to this; or if you don't, it makes a lot of sense to hire out or get some advice from a network consultant.

What you'll see in terms of the firewall vendors — there are many of them here today also. Many will provide or claim 100% security. That is a lie, unfortunately. There is no such thing as 100% security on the Internet, and it's just sort of a fact of life there. It's not to scare you away, but it's recognized that the risk is there. Take all the precautions that are necessary.

It's also very important to monitor a system. What we do a lot with one of our developers is that about 10% of his week is spent just scoping around our system, making sure everything is in the right place and that it looks like it's supposed to look, because oftentimes if there's a security breach you'll be able to see little strange things going on in the system that don't make much sense, and they can often point to problems in that regard.

Another thing that made a lot of press a few months ago was a tool called SATAN, which stands for Secure Administrative something-something-something. It's a sort of "hacker in a box" and it will allow my mother — who is not very Web server knowledgeable — to download this thing, fire it up and act like she's a very experienced hacker and probe some well-known and not-so-well-known security holes in your Web site to see what's there.

Now, this was released on the Internet so that everyone would have it and everyone would be aware of some of the holes. It's a debatable strategy that got the guy fired from SGI. He did it, but what it means is that you can have one of your administrators download SATAN, run it on your Web site, and then get a pretty solid breakdown of what's going on on your Web site in terms of security issues. What to keep in mind is that if you're not running it, you can bet that somebody else is running it on your Web site. So it pays to do that. I put the question mark there because initial releases of SATAN actually have their own security holes in them. By running SATAN, you opened up new problems, so the problem is recursive. New versions of SATAN have since fixed that, but you never can be too sure.

Moving ahead into information content, the ultimate purpose of this site. I don't want a Web site so I can know about ISPs; I want a Web site so that I can serve information out to my customers or users or my people internally. Now, of course, these are going to be written in HTML, which is the Hypertext Markup Language — generally, fairly straightforward, not to be intimidating. But there are lots of fifth-graders who have their own home [inaudible] and are pretty HTML-savvy out there. It's not brain surgery, however, and it pays to know what you're

doing.

The way most people learn how to write HTML — and frankly, the way I learned to write HTML — is you bring up a Web document on one side; you click “View Source;” you bring up HTML; you go, “Oh, to do that, I do this and to do that, I do this. Great!” and you’re ready to go. However, HTML is based on a number of very well-defined, very rigid specifications that say, “This is how to write HTML. This is how to write it well.” That’s all fine and good, especially given when a browser manufacturer writes their HTML rendering engine. They refer to the specifications that say, “This is how this should be written, and this is how it should be displayed.” Then they go forward and do it based on that.

Now, what you’ll find is that different browsers have different quality rendering engines. I just learned that this has been illustrated very well by *Netscape*. *Netscape*’s rendering engine in version 1.1 and 1.2 was one of the most robust rendering engines there was for HTML. So you could do things wrong — you could forget the closed quotes, or keep brackets open or things like that, and *Netscape* would say, “Oh, I know he meant to do this, so I’ll make it work.” This is good because that means that more Web sites out there are functioning properly.

The problem is that if you write your HTML and then look at it in *Netscape* and everything looks great, you never know. If someone comes in using *Quarterdeck Mosaic*, or using something from *Spry*, or the Microsoft browser, [you don’t know] what it’s going to look like to them because their rendering engine may be a little bit different.

Incidentally, because of this, *Netscape* has de-tuned their rendering engine for *Netscape* 2.0. The new version will break on things that the old version did not break on because of this. It was sort of interesting to go through even our own Web site and to see some of the newer links that we’d put in there where it wasn’t quite right because we just all use *Netscape* — not the safest thing to do. Bottom line here is: it makes sense to know what the specs are if you’re going to be writing a lot of HTML; and to know what they mean so that your content looks as it’s supposed to look and works for as many of your users as possible.

Also, as of maybe February/March of this year, we’ve been keeping stats on our Web sites for the sorts of browsers coming in. Even in March, 98% of all our accesses were one of three different browsers in *Netscape*, *Mosaic*, or *Lynx*. Actually 10% of all our hits are from *Lynx*, which is a text-based browser, so one out of ten of our users don’t see any of the fancy graphics that we’ve paid so much money for.

So it was pretty easy back then; you could do your content, bring up the three browsers, look at it — okay, you’ve covered 98% of everyone who is coming in, you’re good to go. Today it’s about 15 to 20 different browsers to get to 98%. So it’s much, much more difficult to bring up all the different sorts of browsers and figure out what’s going on there. The spec compliance helps a lot. In terms of the actual content of course, it’s important to provide useful information with significant detail — but that’s the source of an entirely different talk that I won’t be giving today.

Moving on to information structure. Oftentimes information structure can be just as important, if not more important, than your actual content itself. Why? Because if people can’t find the content that they’re looking for it might as well never be there. It pays dividends to pay attention to what’s going on on the structure side and to put some thought into that to make sure of that.

For example: I’m a user who is looking for products specs on the “ABC widget.” Well how are they going to get to that? Is it going to require 10 or 15 clicks? If so, they are never going to find it. Early on, it was said that any page on the WorldWide Web was no more than eight clicks away from any other page. That’s probably not true anymore, but eight clicks is a lot; you can get very far. So [when] you’re requiring users to go all around, it can be very, very difficult for them to find it. Things that can help out here are a simple Home Page that will

quickly direct them to different areas and appropriate levels of detail. You don't want to have a Home Page that's 25 pages of text long, so I've got to filter through everything in order to find what I'm looking for. But you also don't want to have just menu, menu, menu, menu, content on the bottom. So it requires a bit of a mix going on there in terms of how much content you're presenting at which levels of detail, and how to give users clues in terms of which direction they're going in.

Simple user navigation can often be helped by things like a simple toolbar at the bottom that will bounce to particular spots in your Web site, and a search engine being able to search for specific terms or keywords to be able to find what they're looking for very fast. Again, any questions?

M: [inaudible]

Matthew Cutler: Good question. How do you overcome the different standards, HTML 2.0 versus 3.0? Interesting point, because you assume that there's a standard for HTML 3.0 and there isn't yet. What we actually do on our Web site — if you're not using 3.0 tags in terms of tables and centering and backgrounds, you look really old and stodgy. But at the same time, you're really only writing for about two or three different browsers. So for the pages that we do 3.0 tags, and we have links to 2.0.

What we have to do is maintain separate versions of our pages and in the different compliance standards. The issue that I was touching on was that landscape has been incorporated into a lot of 3.0 — and arguably even 3.0 and beyond ability — and a lot of the browsers can't keep up, the problem being that there is no officially-recognized IATF-certified RFC for HTML 3.0 yet. It's in the works and supposedly coming in any day now. It's an issue.

There's some more advanced content-creation tools that are coming out that will allow you to, depending on the browser coming in on the fly, present it as appropriate. This will become even more problematic when you have things like *Java* in your Home Page. I'm not sure [inaudible] you'll hear a lot about that at this show, but if you're using the *Java* browser and go to Sun's Home Page, what you get is a different Home Page, which is like this information application where buttons pop. It's very neat and very cool, and it detects it on the fly. But what will probably start happening is the newer generations of browsers. When they make requests, they'll say, "I'm looking for this document, and, oh by the way, I understand the following things: I understand GIFs; I understand JPEGs; I understand HTML 3.0 and *Java*," so that your server will be able to respond accordingly. Both the market and the technology are moving in that direction.

M: [inaudible]

Matthew Cutler: Okay. The question was, "How many people do we have on staff maintaining our Web site?" Well, because we're a Web development company, you could say virtually everyone maintains our Web site, but we have a team of about three or four Webmasters who are primarily responsible for that. net.Genesis started a sort of thing called the Webmaster's Guild, which is the first professional association of Webmasters; it's now an independent organization. We're actually going to be having a meeting on Wednesday night here. Stop by the net.Genesis booth if you'd like more information about that.

What we determined, as part of the Webmaster's Guild, was that the Webmaster is really not a person but a function of six different disciplines: contact, creation, technical implementation, information architecture of graphic design, project management, and marketing. Those are the functions that are embodied; you can divide it up across as many

people as possible.

The second question was, "Are we currently programming in *Java*, and what's the timeline until that becomes widely implemented?" Yes, we are currently doing *Java* development mainly internally just for us to get up to speed on it. How long before *Java* becomes very widely implemented? It could be very soon based on what is going on out there.

The fact that Netscape has licensed *Java* and is incorporating it into their 2.0 browser means that it's going to be very big, very quickly. There's still a lot of things going on in terms of the underlying *Java* technology. It's still beta technology for virtually every hardware platform, and it'll need some bug tests to be brought through it. I'm not sure how many of you have really experimented with it. It's cool and it's cute right now, but I've yet to see a really interesting application developed with it. Until those sort of applications start coming out and there is a compelling reason to be using *Java*, it'll be interesting.

M: [inaudible]

Matthew Cutler: The question is, "Is there a natural progression from HTML to *Java*?" Yes and no. *Java* is really a quantum leap that supersedes HTML. HTML is just a little piece of it, but it's C++ in operating systems and all these things too.

M: [inaudible]

Matthew Cutler: The question was, "When do I think HTML will die and something else come up?" My crystal ball is a little cloudy on that one. It's tough to say. What will start happening, I see more and more, is there will be more and more format-supported PDF, *Java*, etcetera. And what you'll see is there will be probably less strict "this is only HTML mechanism" and more of that dynamic information exchange. When you make a request, your browser will say, "I understand the following types of information formats." And then it will make intelligent decisions and say, "Okay, this guy is running a high-speed server or high-speed browser on a fast Internet connection. I'll send him the PDF file because that will look better," versus, "Oh, he's on a very slow modem. I better send him the HTML because it's smaller." Things like that. But that's a little bit in the future.

M: [inaudible]

Matthew Cutler: The question is, "Will the browser always be there in terms of a single window presenting the content?" Tough to say. There is some interesting movement towards the browser being integrated with the operating system on a very fundamental level. So what will start happening is that the distinction between hard drive and network and between browser and desktop gets very, very blurry. You'll get to the point eventually where you don't care where your content was at; you just want your content. It should be transparent, but that's further down the line and a little bit outside what we're doing here. We've still got a lot to do.

For [inaudible] makes very good press as well. This is the netiquette of what's going on in the Internet and how not to piss the general community off. It's generally overblown; a little bit of common sense will make things a lot easier. By the way, do not use spamming as an example. If you don't know what I'm referring to, it's been a long time since this has happened.

Avoid over-hyped advertising or traditional marketing messages in general. The attitude of taking your 8 1/2 x 11, slickly-done glossy that you're going to be putting in *Time* magazine, scanning that in at 300dpi as a JPEG and sending it out to the Web, is a quick way not to get a

lot of users. Obviously it makes sense to have a little bit more consideration and think about the medium there.

Avoid extraneous images in multimedia. You often find multimedia for multimedia's sake; in fact, about probably 95% of all CD-ROMs fall into this category, or [the category of] multimedia CD-ROMs where they're just throwing in video for the sake of doing it, and it doesn't really add much to the message. When you're using the Web, content counts because the bandwidth issues are very, very real. So on your Home Page, having a very large graphic that's the first thing that downloads — and you'd be surprised, a lot of companies do — is also a quick way to slow down users. If it takes 45 seconds to open up your lead page, people are going to go away.

Overly-nested information is one thing to get away from. That's what I touched on [earlier] in terms of information structure. Information that's really, really deep in the hierarchy is oftentimes difficult to find and won't be found. And non-intuitive links, you'll see a surprising number of these as well. You'll see a relatively innocuous link; you click on it and suddenly you're downloading a 2.5 megabyte video file or FTPing something that you didn't know about. You like to set the users' expectations of what to expect when they click on this link. And that's just, again, common sense.

For advanced features, things like form support or image-mounts or general CGI scripting... Forms are the forms that allow you to type in information and submit information back to the server.

CGI image-mounts are clickable images which allow you to present like a map of the United States, and depending on where you click, will bring up a different Web page.

And then CGI scripting involves a lot more. What CGI stands for is the Common Gateway Interface. CGI is not a programming language. It often gets interpreted as one, but it's mainly just a specification that defines how Web servers can talk to other programs and how other programs can talk back to it. CGI programming is true coding, not HTML. I mentioned fifth-graders before, and I would be shocked if there would be many highly-proficient fifth-grade CGI coders. Being able to do CGI requires not only a coding background, but also a familiarity with the specifications. As embarrassed as I am, given my engineering background, I cannot code. So I am CGI illiterate. It's very technically complex. But the flip side of that is that CGI is what really enables Web sites to be interactive.

A term that I coined a little while ago, to applause as well as derision, was "interpassivity;" that most Web sites out there are not that interactive, even though the Web is this great interactive medium — but it's just point and click. They're lacking, and what they're lacking is the interactive element supplied by CGI. We're really engaging the user and doing some sort of user-feedback, dynamic document creation discussion forms; things like that. It enables search functions, it enables on-the-fly generation, database-driven Web sites, database integration, as well as discussion groups.

Right now, this is where my company focuses. We have products that address a couple of these issues that take away a lot of the technical issues and make it easier to use as an end-user. But that's where — just a little bit of a background with what we're doing is — we're trying to make this area easier because we recognize that it's often very, very painful for a lot people out there. Questions on CGI?

Okay. Into ongoing maintenance. Ongoing maintenance is often the larger task of having a Web site. The idea is to get consulting requests of people saying, "We have 10,000 documents and we want to get them into HTML and put them on the Web right away." The first question to ask now is, "What happens next?" They say, "Next?" We say, "Yes, you have to maintain these things down the line, keep them current, keep them updated and keep them running. And in the long term, that's probably going to be a much greater cost than the initial setup." For

HTML, you have to make sure that your HTML is verified; that it's specification compliant, "HTML spell-checked." There are a number of freeware utilities that do that right now. None of them do it especially well, unfortunately, but expect to probably see some commercial development in that area soon.

Link integrity is a big one. Link integrity is that if you have a link on your Web site, it needs to be pointing to where it's supposed to be pointed. As a result of some earlier studies that we were doing internally, we discovered that at any one time between 20 and 25% of all links on the Web are invalid, so one out of four mouse clicks will get you to an error page. That's not very good.

Link integrity can be compromised for a number of reasons. It can be involving content — you're adding content in, etcetera. The WorldWide Web is exactly that — a web of documents interlaid over each other. A document in each [inaudible] doesn't mean anything except in relation to the documents that it's linked to and that it links to as well. So as you start adding content in, putting more nodes into this web or moving things around, you're breaking the threads out. It becomes very, very easy for links to become invalid. Now, if you have four or five Web pages, it's pretty easy to every morning come in and click through your links. Everything's there; cool, rock and roll. For us, we have several thousand Web pages on our Web site. IBM has between 25,000 and 50,000 pages on their Web site. You can bet that it's not an easy task to do manually and that there's got to be some management to do that. There are a number of tools coming out to help you with that as well.

We also have hardware errors. If you're linking to external sites, their site can go down. You're not responsible for that, but users from your Web page get errors because the Web site is not there. Well, that's a problem, and you need to be able to detect and know where those links are in order to insure that your users are getting as many correct links as possible.

You have things like feature maintenance too. Let's say you put this really good search engine in, right? And the search engine generates an index based on your content. Well, then you add content and move content around. You need to make sure that search engine index gets updated so that it reflects your current content situation. We'll see sites — and some very, very large sites — that you go into the search engine, search on a word, get a link, click on that link, and that one's invalid. So they string you along and then drop you on the floor because their search engine hasn't been kept current with their Web site.

And finally, feature maintenance in terms of [inaudible] discussion areas. You want to keep the discussion areas fresh, with recent posts in there. Having posts that have been laying around for four or five months is oftentimes not very effective.

And site usage analysis, which is receiving a lot of attention in the media and a lot of development there, comes with the ability to generate a marketing approach based on your Web site, and that is very important. That's an ongoing maintenance task.

Moving on to the capital costs associated with this. How much is it going to cost?

M: [inaudible]

Matthew Cutler: The question was, "Is it common practice, when you get an error from your Web site, to log it or to send e-mail to the Webmaster?" There are error logs kept, and you can configure them as appropriate. What you'll oftentimes see is that they present a lot of information which isn't necessarily worth keeping, like if someone types in a URL that doesn't exist, but they're looking for it on your Web server or they're looking for a page that's not there. You'll get error logs of that. But that's a good way to do it. You can also set up e-mail gateways and things like that. I'm not sure of any commercial products that do that today do it very effectively. Any other questions?

M: [inaudible]

Matthew Cutler: The question was, "There are a number of tools available right now, or products, that allow you to create [inaudible] documents without actually having decoded." And it's true, there are a lot of them. They are simple, and I'll touch on them a little bit towards the end, but there are HTML editors which are point-click interfaces. To that what we have seen — for us — when we do our HTML generating, we use *EMACS*, which is a UNIX text editor. It's a good development tool, but it's about as bare-bones as you can get. The main reason [we use *EMACS*] is that with most of the HTML editing tools either the interface is so clunky that in order to do a tag, you've got to Alt, Shift, Drag and Header each one — yes, okay, and click — and in [inaudible] you get "Bracket, Bracket..." It's easier, if you're familiar with it, to just type it in. There are some newer generations that are coming out that have more capabilities and better interfaces, but we haven't found one that we're very comfortable with.

You often find ones also that don't fully support the feature set, or that are limiting; that you can't do tables in or that they do things wrong. For instance, *Microsoft Internet Assistant*, which allows you to save *Word* documents as HTML, I'll use sometimes to quickly create documents; but I'll create the HTML, then bring it up in *EMACS* and spend ten minutes going through it to make sure that everything is right and to change things as I like them.

There are also fully-integrated browser server packages. [Inaudible] sells one. What they have is a front-end creation tool and a server. The problem there is that what you're doing is dependent on each other. Your content-creation environment presupposes that you have this certain type of server, so you're locked into their solution; you're locked into their updates and things like that. What we really like to maintain, and we think is very important, is the ability to control and maintain your content as freely as you choose. Having solutions that tie you into doing things the way a certain company thinks you should do them makes us nervous; but depending on your environment, that may make sense for you.

Closing up on the building issue right now, for capital costs, you have your Internet connection that will get you multiple [inaudible] this way. You have your installation fees. Getting the phone company to install the phone lines, which is actually — as we're finding right now as we're moving office spaces — the biggest part of the entire problem; getting them to actually do it. But they charge you when you have required hardware. In order to get your Internet connection functioning, you need a thing called a CSU/DSU and a router, and those can be very expensive pieces of hardware. Then you have your line, as well as your provider fees. So you're paying fees to your phone company for access to their phone lines and then provider fees to your Internet service provider for them taking care of all your Internet connection stuff. So that component can be very expensive.

A full T-1, first year including installation, costs between \$34,000 and \$36,000. [These prices] are about average, and not unheard of. Prices are coming down as the competition is heating up, but it's still a very, very expensive proposition, which is oftentimes a reason people choose to outsource the information, their Web site contact [inaudible].

You have the cost of the host computer hardware and the associated technical support. Let's say you're a Macintosh graphic design house, but you decide to go with the UNIX workstation to develop off of. If you don't have any UNIX expertise in-house, you're going to need to hire out to do that, so that could be expensive as well. And your computer — you can get a reasonable Pentium desk-top system with a good amount of RAM for about \$2,500 today. You can also get a pumped-up [inaudible] or Alpha station for 25, 30, or \$40,000, depending on what configuration you get.

Building costs also involve human resources.

A Webmaster is a big one. We get lots of requests for that. For a while, when we were doing more consulting — we do relatively little consulting now — we could almost have started a division called “net.Genesis Headhunting,” where all we did was refer UNIX experts around to the companies that were looking for them because they’re in very high demand right now. The reason why we didn’t do is that we were hiring them all internally ourselves, so we weren’t passing on good people. But good UNIX programmers, good Webmasters, are very difficult to come by these days and are in very high demand. So if you have them internally, treat them well because they’ll be getting good offers from other sources. There’s a forum where lots of Webmasters would meet, so for companies that are looking to hire them, that they have a place to look towards.

[Inaudible] a cost of the content generation. Not only are each [inaudible] CGI, but also how much content are you going to custom-create for your Web site? What we find is that we have a lot of marketing material as a company, but there’s tons and tons of original content that only appears on our Web site, and that takes good people’s time, and the cost of the ongoing technical maintenance to keep the thing alive, and the time in learning curve associated with getting up the ramp.

As you can see, with all these factors, you can look at the \$24,000 T-I; but when you look at the cost of people here, that can be the greater side of it.

What we also see oftentimes is companies that are putting up Web sites that have these very over-worked, over-stressed UNIX developers or system administrators; they’ll just add Web site to their list of responsibilities without taking anything away. You know these people are already about to crumble. Web sites can actually require a lot of attention, even very, very professional Web sites, and people need to know what they’re doing. So if you’re going to be assigning someone to keep this thing alive, make sure that you give them time in order to do that. It can be as much as 10 to 15% of a week.

There’s lots of companies — for example, *Hot Wired*. I think they have there over 45 people. *Hot Wired* is an on-line magazine, and every single person on their staff is contributing to their Web site. So they have 45 “Webmasters,” depending on how you look at it. Okay, that’s the end of the building session. Any overall questions on that?

M: [inaudible]

Matthew Cutler: Yes. Oh, very good question. The question was, “How long does it take to get IP addresses?” In order to set up your Web site and get connected to the Internet, you have to deal with an organization called the InterNIC. What the InterNIC does is register your domain name, set everything up, etcetera. It used to be free to do that, but because they were getting so deluged now it’s \$50 per year, per domain name.

For a long time, it initially took about a week. And then they got flooded, and they took about six weeks to process a request. Lately they’ve been out about four weeks. But we’re moving office space right now, so we need to have some of our DNS stuff changed. We submitted our DNS change four weeks in advance, anticipating that it would take four weeks and that we could make the move in the meantime. Well, the InterNIC, being the InterNIC, turned it around in 48 hours. So what happened was that our stuff got changed over much, much faster than we expected it to, and we weren’t ready for it. That caused problems down the line. So it’s very inconsistent. Give it time, but understand the issues there.

What’s also interesting is that the way that it works is that the InterNIC makes changes, and then they propagate throughout the Internet. So even though the InterNIC changed our DNS information in two days, it took two weeks for it to propagate through in fact, until anyone really found out about it. So it was even too late, once the change had been made, to

submit a request to change it back because that would then take two weeks longer to filter through. So there is a bit of a time delay there. It's interesting to deal with. But even we, as a Web development company, run into problems with that whole situation.

Yes.

M: [inaudible]

Matthew Cutler: I don't understand what you mean by "PC platform."

M: [inaudible]

Matthew Cutler: The question is, "Does the difference between having a Pentium Web server and a UNIX workstation Web server — what's the degree of magnitude to justify the cost of that additional investment in UNIX?"

Well, in general, if you're really going to be investing to have everything internal, even a very high-end workstation is going to come out in the wash. But the issue there is not cost, but stability of what you're doing. Would I allow my corporation to publish its corporate Web site on a PC platform? No, I wouldn't. We did for a little while, running a Pentium system with an operating system called LINIX, which is a free version of UNIX. It's a great operating system, but even that has its issues. We were on a DEC Alpha running OSF-I.

For us, because we're a [inaudible] company, our Web sites are a really core component of our business. I wouldn't trust anything else but UNIX. When you look at it, to get a workstation that's pretty well-loaded, it's about \$7,500. To get a pretty well-loaded Pentium system, you're looking at \$3,000 or \$4000. Your delta there is small. What you also have, dealing with the UNIX platform in general, is that software for UNIX is much more expensive than for other platforms. For our product's pricing, one of our products is \$500 on NT, but is \$900 on UNIX. It's just the development issues and the general sort of accepted normal practices in the different computing environments. Overall though, because there is so much time and energy and so much manpower involved in it, it comes out in the wash. It really does.

Yes.

M: [inaudible]

Matthew Cutler: About platform?

M: [inaudible]

Matthew Cutler: Yes, what about it?

M: [inaudible]

Matthew Cutler: Oh, okay. The question was the feasibility of using Macintosh as a server platform. I had a Mac for a long time; I'm a big Macintosh fan. But when I was really doing some good processing on it, I was lucky if I could go a full day without having it crash, and I think that's an issue if you're going to have a high-traffic Web server.

For some of the lower-traffic Web servers, that's fine. There's more and more Macintosh development occurring these days. Star NINE makes a good Web server for the Macintosh platform as well. But it's more of an issue of general system stability.

Through my friends at school, I've learned a lot about how a Macintosh works on a very

fundamental level, and for that reason I wouldn't trust it. I understand how Windows 95 works on a very fundamental level because my whole system came down just a few nights ago — interestingly enough — and I wouldn't trust that either. But I do understand how NT works, and I do understand how UNIX works. On a fundamental level, I trust it. When it comes down to it, I don't trust Macintosh, but that's more of a personal preference. You'll find Web sites out there that are run on Macintosh, but you won't find any very high-traffic Web sites or large-scale Web sites to the best of my knowledge. All of them are running UNIX, and a very few are running Windows NT.

In general, because so much of this stuff is untested and it's all new ground, having precedents set is very important. You know, a lot of companies will say, "Oh sure, it's just Internet. It should work." Well, there's a lot of new complications that are introduced by the Internet, so it pays not to be a forward thinker in certain respects. The purpose for our company is to get out all the kinks so that companies that are just looking to do regular business on it, can do it effectively. Any other questions?

Yes.

M: [inaudible]

Matthew Cutler: Oh, good question. The question was, "What do I consider a high volume?" Again, of course, it depends on the platform, but generally high volume is more than 30- to 45,000 requests per day. But it depends on really what's going on.

Some people will say high volume is more than 10,000 requests per day. We have Web sites out there that get well over a million hits per day. Our Web site gets tons and tons and tons, so it depends. And it all depends on when you're investing in your hardware platform. [You may think,] "Well, you know, I'm a small company and I'm providing this relatively small page. I'm not going to be getting that many hits." Well, yeah, today you might not be getting that many hits; but in a few months or in a year's time, how much traffic can you expect to be receiving? And how is your hardware platform going to mature to handle that? Expandability of your hardware platform is a very important issue.

Yes.

M: [inaudible]

Matthew Cutler: Sure, we'll move on in about two minutes.

M: [inaudible]

Matthew Cutler: The secure unit versions of...

M: [inaudible]

Matthew Cutler: Oh.

M: [inaudible]

Matthew Cutler: Right, right.

M: [inaudible]

Matthew Cutler: The question was [regarding the] issue of network security of operation system security; is there going to be a market for government-spec UNIX platforms that are used for serving their stuff? Tough to say. I would think the security issues are probably overblown. There are military spec computers that you can drop out of planes that will still work, by the way, and I know companies that use them. But that's definitely overkill.

You hear issues in terms of UNIX being not as secure a hardware platform. It's actually the reverse. UNIX is the most secure because it's been in existence the longest and has been poked at and tweaked and touched by the most hackers. Windows NT hasn't gone through that process yet, so it remains to be seen how well that holds up. The issue is, it's probably overkill. I'll move on; I'm sorry.

In terms of buying Webs that are outsourcing, I'll go through the general requirements, talk about the issues of Internet consultants and touch on the external costs.

The general requirements, if you're going to be outsourcing, is that you need a system outline. A system outline involves a short-term plan as well as a long-term plan. It is very important to differentiate between the two. Again, if I'm moving too quickly, please feel free to ask to slow me down.

Short-term plan being: what's your plan for the minimum amount of Web site content? What can you comfortably publish as "www.mycompany.com" and not be embarrassed about it? What's your long-term plan? Oftentimes companies get the two confused and say, "We want our Web site to be fully secure and commerce-enabled; credit card transactions; full order processing; catalog, etcetera, etcetera." And it says, "Okay, that's a good goal to work toward, but let's figure out a shorter-term goal which is a little more realistic to hit." And then you can build on that, moving forward. It's very, very important to do that.

What we recommend, based on our engineering backgrounds, is to do a prototype system where you do a mock-up of a system which suggests some of the functionality; evaluate that; critique that; show it around internally, and then build the short-term plan and the long-term plan.

You have to have some ideas about system structure — how that's going to look and of course, what the contents are going to be. As a consulting company, we would get a lot of people, a lot of large companies, that would say, "We want a Web site. What should we do?" And that's an entirely different problem of deciding how the system is going to look, how it's going to fit into the organization versus how you're going to develop it technically.

You'll see today that there is actually becoming some differentiation in the Web consulting marketplace in terms of their Web consultants — that's a WorldWide Web marketing consultant, that's a WorldWide Web advertising consultant, or that's a WorldWide Web technical consultant — so that you can differentiate between them. And oftentimes you'll see consultants that bill themselves as [inaudible] "We'll do the whole thing. We know every aspect of your business. We know every aspect in this technology." Chances are they are going to be pros at one and amateurs at another or amateurs at all of them, etcetera. It's very rare that you'll find a complete consulting company that can effectively do every single aspect of Web site design. But I'll get to that in a little bit.

Towards content definition, there are issues involved there. It'll help a consultant a lot, the further along you can bring them, if you can say, "This is what the pages are generally going to look like. We want to have a products area and a services area and a support area," something like that to help to give consultants a better idea. And even to specify links if you can say, "This area is going fall into this area in the following manner," and to have the information in electronic format.

My consultant company bills out at \$125 per hour. It doesn't make sense to be paying us to do your typing. So if you don't have your content in a readily-usable graphic format or

electronic format, then it's important to convert that into that environment until your consultants can work with it. And depending on the company, we've worked with companies that today are powered by PDP-11s, some of the very, very initial business work computers. For us to get the content out of there is very painful, but it needs to be paid attention to.

What we recommend, and what we actually require for any consultant work that we do, is a design document. This comes out of doing lots of design experience in different fields at MIT. What it does is really provide a clear plan of action. It's essentially a functional specification that says, "This is exactly what is going to be delivered." What it does is set the goals, assess the capabilities and set real deadlines for the system. It should be a significant portion of the budget in mechanical engineering and many other fields of engineering. The design phase of a project should take about 80% of the time and money involved.

For mechanical engineering, it's very important because changes down the line can be very painful. But that's true here [as well]. What we do with the design document is sit down with our client and really nail down exactly what is going to get produced: when, why, how, what dates, what the payment figures are, etcetera, because what happens as you get into these projects, whether you do it internally or externally, is that new ideas come up, or people get excited about it and have new concepts and want to move things around. It's really a very, very effective means of completely scattering the entire development process and making sure you'll never get your Web site done.

So what we do is say, "This is our design document. This is what we agreed to sign off on. If there's any changes down the line, we can evaluate it in terms of the design document." [Later we can] say, "Look, if you really want to make this change, well, let's see how it's going to affect the delivery; let's see how it's going to affect the budget." What you'll often see is that very, very small changes can have very big ramifications like, "Oh, we know we told you to do the Home Page this way, but we decided that we just want to do it this other way." Well, it's just one page of HTML, right? But the Home Page determines the entire structure of the system down below, so you can spend 15 minutes changing an HTML page and spend days changing the rest of the HTML hierarchy. So it's important to understand these things.

Also, as new ideas come up it's easy to say, "Oh, well that's a great concept, but we need to get this done first, and then we'll explore that down the line. Write that down and remind me when this is all done with." So it'll really maintain the focus, and that's very important and we require it for any consulting that we did or currently do.

For Internet consultants, there are a number out there today. There are literally hundreds, if not thousands in business. We founded net.Genesis in January of 1994, and there are probably about three or four other companies that we knew about in the entire country that were billing themselves as Web consultants or doing Web development. That was okay because there are about three or four corporations that were looking for Web consultants, so it was just as competitive as it is today. But it's really been interesting to see how fast it's grown and how many people have come on board as Web consultants.

You can look out there, and there are hundreds, if not thousands out there. At the show today, there is [inaudible] Interactive; they're the company that did the White House Web site. Direct Results Group — I don't think it's here — they do a Web site which is very cool. BBN Planet is here, and there are more and more and more out there.

To locate Web consultants, an easy way to do it is on the Web. *Yahoo* has a listing of Web consultants that's over a thousand long. *CommerceNet* also has one. What's interesting about the *CommerceNet* Web-consulting pages is that when you register as a consultant, there are about ten or fifteen buttons that you can check as areas of expertise. What you'll find is that every single consultant checks off virtually every single one of them, so it's pretty hard to differentiate. Okay, they have all said they have UNIX expertise — who is really the expert, and

who is really proficient, and who doesn't know what the hell they're doing? It's difficult to determine that.

So how are you going to do it? Probably the best way is to look at existing sites. Go out to an existing site, one that you like, one of your competitors, one that's similar to how you want yours to be. Then write to the Webmaster and say, "Hey, how did you guys do this? Did you outsource it? Who was involved? If you did it internally, what did you think?" And you can get good references that way.

What you'll find, because there's so many new companies out there, is that there's a very broad range in terms of them as businesses, let alone the work that they do — young company, inexperienced people, not even professionals who have done this before. And even though they can produce beautiful work, if they're over budget, over deadlines, if they don't return phone calls, if they're just painful to deal with, then is it going to be worthwhile going with them? So not only be diligent in terms of [evaluating] the quality of the work that a consultant [can do], but also [determine] how they are professionally to deal with. That can be a very differentiating factor.

What we have focused on as a company, very early on, was just that — because we are relatively young and have a lot of that to overcome. So customer focus is very, very important for us. And you'll see certain Web consultants that excel in this and certain Web consultants that do not. It makes sense to choose them accordingly.

You have to evaluate [Web] consultants in terms of their capabilities. What are their main areas of expertise? For us, when we were doing consulting, we didn't do graphic design. We outsourced it all because we don't have any graphic designers in-house. Now it's like when the Macintosh came out as desktop publishing. You bought *PhotoShop*; you bought *Freehand*; and yeah, I'm a graphic designer, rock and roll. It really doesn't happen that way. And experienced professionals are important in different areas.

The size of the consulting company varies quite widely, not only in terms of numbers of employees but in terms of capital equipment — what they have in-house. You'll see like Digital Computer — DEC does Web consulting, and obviously they're a giant organization. You also have husband/wife/dog working out of their garage doing Web consulting. What's interesting to know about this is that everyone is new to this game in terms of the technology. If you meet any consultant that says they have been doing Web consulting for 15 years, they're lying. The Web hasn't been around for that long. The Web has only been around, for all intents and purposes, a little over two years. So for us — we were founded about two years ago — we're dinosaurs in terms of Web years, even though as individuals we don't have very much gray hair. So it's difficult to tell.

And just because it's a small team does not mean that they can't do really great work. What it does mean, if they're a small team, is that they can't take very many concurrent projects. If you're working with a small team and you ask them what else they have going on, and they say, "Oh we have six other large-scale projects in the works right now..." There's only so many hours in a day, and there's only so much a person can produce.

That touches on resource availability. Location. Location is actually a really big one, and there's a lot of debate about this. This is the Web. This is the Internet. There's no reason that you can't do things telecommuting and remotely. We can Telnet into a Web site on the other side of the country and upload content back and forth, and there have been arrangements this way. I've heard about consulting deals that were introduction, initiation, closing the deal, project completion — all over e-mail, all remotely, never even a phone conversation involved. It's possible.

For us as a corporation, we would not be very comfortable working that way. The ability to meet with your client, to sit down and work as a consultant, to see them on a regular basis,

check progress, see how things are going, is very, very important — especially if you're doing an important site or one that's expensive; that has a lot of stuff going on. It's worthwhile.

What we've seen is that the bulk of our consulting clients have been in the New England area, so that they get to be close to us. If we were bidding on a project that was in the Midwest or on the West coast, we just stopped doing it because it was too painful to manage that sort of relationship.

Price. They vary quite widely in terms of price. Any price figures I mention here, you can go out there and find an order of magnitude below and an order of magnitude above. And you can say, "Well Matt, you told me that it was this and I found this guy that said it's..." My company charges out when we do consulting at \$125 an hour or \$1250 a day for off-site work. We get told that's about average to a little bit low. There are other consultants that will go for \$50 an hour or that'll go for \$25 an hour, especially if they're still in college. There is Anderson Consulting or some of the large, large consulting firms that will bill out at thousands of dollars per day — three, five, six, ten thousand dollars a day to do that. So it really depends on who you talk to.

It also depends on the quality of service and what you're getting done. In general, if you're spending \$10,000 a day you're probably spending too much. If you're spending ten dollars an hour, you're probably spending too little, and you're going to be getting what you paid for. So keep that in mind.

And then experience. What else have they done? What other Web sites have they done? Who else have they worked with? In what regard? For us, in terms of our company, when we were a Web consulting company we were technical consultants. We did the very high-end technical work in terms of, well, we're pushing the technology in this regard. Who could we bring in to do that? We would not do a lot of HTML. So it depends on the background levels of expertise in evaluating a consultant.

Previous work and areas of expertise. Do they know UNIX? Do they know Windows NT? Can they HTML author? What sort of CGI have they done? What have they done in terms of software development?

For collateral competencies, this can often be a good indicator of what's going on with a company. Do they write publications? What is their industry involvement? It's really easy for a company to put their head down and just focus on the Web and focus on what they're doing; but it certainly can be very useful if they sort of look at what's going on, on the Web in general, on the Internet community in general, and become more involved with that because that will help them down the line. And that's something that we think is particularly important and that we pay a lot of attention to. We're not just a Web company, but we do a lot of other. You'll see many other consulting companies that do that.

There is a consulting company on the West coast — I forget which one — that organized Net Day, where they're organizing all the Webmasters and Internet people in the Internet community to go out into the general community, to schools and teach and things like that. And that's a really great thing. It's really very powerful.

Services offered. Different consultants will offer system design in terms of helping you structure your system and how that should be done.

Scripting capabilities in terms of CGI, HTML-generation and so on. Obviously most consultants will do that, depending on who they are. Many will offer content conversion facilities to do text, to do image scanning, to do multimedia recording. [Inaudible] you have training videotapes and converting into a QuickTime movie. A lot of consulting companies will offer those. Again, those are areas that we do not offer at all; that's not our focus. So it's just a matter of figuring those out.

Others will offer graphic design. There are lots of issues involved with graphic design on

the Web and how to be a good designer. What's the difference between a [inaudible] and JPEG? There's actually a very big difference, and there are certain situations where a [inaudible] is more appropriate than a JPEG and vice versa. There's little things like the difference for, I think, a [inaudible], which is a relatively dumb image format. For a file size of a file that's 63 colors, there's a big jump between 63 colors and 65 colors, but almost no difference between 65 colors and 67 colors. Why is that? Sixty-four is a power of two, and as the bit count goes up your file size balloons. That's just a little, small tip that's important to know when you're publishing on the Web, because bandwidth counts. And the image quality between 63 and 65 is pretty much indistinguishable, but the file size, how long it takes to download, can be very large. [There are] lots of little street-smarts that help, so the services offered can be important.

What we did when we did our graphic design is that — we don't have any designers in-house. We worked with a small design firm and sat down with them and told them, "This is the way to do design on the Web. These are the technical issues," and gave them constraints that they worked very, very well with. We have been very happy with the work that they've done. Issues like, "We have a [inaudible] and we want to do a gradient." Well, you can do a gradient that goes from gray to black that has 150 different colors in between, or you can do like a little speckle where it's just two colors that gradually intermix. Now, obviously the two-color one will not quite look as well, but it'll be much, much smaller because you're using two colors versus 150. [These issues are] things that count, things that add up.

Content hosting. I actually took out a slide about content hosting, but I wish that I hadn't. Many consulting firms or ISPs will do content hosting, where you rent space on their Web server. You rent space on their Internet connection and locate your content remotely.

Now, there are a bunch of issues involved there. First off is: what are you getting for it? What sort of hardware platform are they using? Are they using a high-end workstation, or are they using a whimpering Windows 3.1 machine? What sort of Internet connection do they have?

They could be content-hosted by IBM or BBN. If you can get [inaudible] of their backbone T-3, that's pretty nice, but it's very expensive. Are they using a 56KB line where your content is not going to be served that quickly? What sort of Web server are they using? Many content-hosting firms will offer secure Web servers, and in order to run off that, you'll pay more. Do they offer multi-hosting capability? Multi-hosting is the ability, when you registered a domain name, to have multiple domain names at a particular machine. It's very much in vogue to have "www.mycompany.com," and if you don't have your company name, all hope is lost. It's really not true, but people do pay a lot of money to get rights to certain domain names. But if you're content hosting, what you'll have is multiple domain names pointing to the same machine, and that presents problems. You need to do certain things technically in order to pull that off very well. Certain companies will provide that; other companies won't, where you won't be able to do exactly what you want to do.

More important than that, though, is the degree of access you have to your content. Any time when you're hosting multiple people's information on a single Web site you're going to have different people coming in and editing the information, which presents security problems. So you have to ask how much control you're going to have over your content. Will I be able to update it freely? Will I have access to the CGI BIN directory?

Many of our clients for one of our products [inaudible]. They use that form because it eliminates a lot of the security holds if they're in ISP, in terms of CGI BIN directory. So you can imagine investing all this money putting a Web site up and then realizing that you don't have access to it, that you can't do the scripting that you want to do, that they won't let you install the software, etcetera. Suddenly it doesn't become such a good deal because it's really restraining. So it pays to ask all the right questions there.

There are lots of companies here that do content hosting. Ask those sorts of questions. You'll see pricing all over the place. You'll see pricing for ten bucks a page. You'll see pricing for \$200 per megabyte transfer. The pricing models vary. Some of them do [pricing] based on how many hits you get. [Depending on] how much of your bandwidth you are using, they'll charge you more. Other ones charge per page; other ones charge per amount of hard drive space. It's really all over the place. But you'll get different sorts of levels of service. You also get 24/7 support from some and not from others. If the Web server falls over at 2:00 a.m. on a Sunday morning, who is going to be there to bring it back up? Is that going to be possible? If it dies on 5:00 p.m. on a Friday, is your content-hosting company going to be gone for the weekend and your whole content down all weekend? There are certainly situations where that can occur.

For the costs of buying a Web site, you have your consultation fees, obviously, paying for the people's time that they're spending with you; the cost of the HTML generation; the cost of CGI scripting, which can become expensive depending on what you're doing. Are you doing some pretty general CGI scripts? Are you doing some very, very specific, very, very complex scripting? How is that going to take place?

Custom development. The question was asked earlier about *Java*. You'll be seeing more and more consulting that falls under the custom development as *Java* becomes more important, because *Java* is just another programming language. People will be developing custom *Java* applications as opposed to straight CGI scripts.

Then you've got the costs of content hosting and the issues there, and then cost of technical support down the line.

What I didn't touch on is [inaudible] a Web site internally. You could pay for network consultants to come in or to administer your site remotely so you don't even necessarily have to encumber all of the maintenance internally, but you can externalize that as well.

Before I go on to both, I sort of ripped through the buying aspects. Any questions on buying? Okay.

This addresses the issues of what to build, what to buy, and what else is out there that's useful. Of course, this is generally going to be the most appropriate route to go down in terms of one form or another, but it really is dependent on what you have internally versus what you can get at externally.

For internal investment, you can train or acquire in-house staff to do things like basic system design and the basic layout, to do a lot of the content generation and to do some of the ongoing maintenance. One thing that we have found quite a bit, especially in terms of large corporations, is that you'll say, "What do you have in-house?" And they'll say, "Nothing, we don't have anything internally." But the Web and the Internet are really cool stuff and people are very, very excited about it, so many people will actually have Internet experiences outside of work, Internet experience without their bosses knowing about it; or if they don't have that much experience they're very jazzed to learn about it. So training in-house staff can often be a very attractive way to go because you have staff that's motivated to do it and think that it's fun to learn.

Of course, there's the issue of how exactly to train them, which brings up a lot of possibilities as well; trade shows is one of them. But we've seen a really, really positive response from corporations. By adding something else to someone's task list, you're teaching them a new skill that they find very valuable and interesting to work with.

For outsourcing, you can seek experienced assistance in things like overall system design and project planning. If you've never done a Web site before, and chances are you haven't if you're doing an external Web site for the first time, it helps to sanity-check your ideas. Say, "This is what we want to do. By the way, you're an experienced Internet developer — what do you think?" And usually it should be just a check-off. But oftentimes, because someone won't

fully understand the capabilities of the technology — because a lot of Web technology and Internet technology has very real limitations — they expect things on what they want to do with their Web site that aren't possible right now. You know, "I want to do 3-D interactive gaming with real-time video." It's going to be difficult right now. It's possible, but it's probably something that's a little bit further down the line. But even smaller issues can come up and can really bite you if you don't get those checked down the line.

Project planning. How long is this thing going to take? In general, because it's just a Web site and it's just HTML, people will tend to under-budget for timing — "It shouldn't take that long to do this." But these things can really be very time-consuming and can really need to be planned accordingly. Not only in terms of time, but also you have your technical team doing your technical development; you have your content team doing your content development; you have your marketing team integrating the messages with the marketing program; you have your graphic designers graphic designing; on and on and on, and you have all these "cooks" involved and accordingly, those appropriately can be very, very important and very, very difficult actually.

Technical assistance is important in things like systems setup. A UNIX workstation is not like a Macintosh. Pull a Macintosh out of a box, plug it in, turn it on, and you get the happy Mac. You're ready to go, right? Not that way with UNIX workstations at all. It's oftentimes very difficult to set them up correctly. If you don't have a lot of experience doing that for something like a Web server, it often pays to hire a consultant just to do that, because if your fundamental hardware platform is not properly configured, if your foundation isn't set and it isn't stable, you can run into very real problems down the line. And you can also run into very real security issues with that as well, if it's not properly configured.

Obviously, technical assistance in terms of CGI scripting for certain types of CGI scripts helps. And it's for any custom system integration too. If you're tying in databases, things like that, it's very useful to have someone who's experienced with the database and experienced with what development to bring the two together in an effective way.

For commercial tools, there are lots of tools being offered on the show floor today and I encourage you to go out and check those out. There are author utilities like SoftQuad's, *Hot Metal* and *Hot Metal Pro*. That's an issue that I mentioned briefly in terms of editing tools. Check them out if you're interested in looking at those. Put them through their paces. Oftentimes, especially with these sorts of tools, you may want to get evaluation copies of them. So get an evaluation copy, hand it over to the Webmaster and see what he thinks of it. If he likes it and thinks it'll save a lot of time, then go for it. If not, then you know that you didn't have to spend all that money on it.

You have content conversion environments, and what content conversion environments will do is take large pieces of existing documents and translate them into HTML. Interleaf has a product called *Cyberleaf* which is actually very, very cool. You can drag *Frame* documents, *Word* documents, *WordPerfect* documents, and a very cute, animated result will pop out in HTML.

There are certain restrictions to know about these, though. HTML is a semantic market language. This is sort of an uninteresting point to debate at cocktail parties, but HTML is a semantic market language as opposed to something like PostScript, which is a literal market language. By literal, it means this word should be at this position on the page, should be in this font, etcetera; it exactly specifies, whereas a semantic market language really specifies things in terms of function: "this should be important; this should be emphasized; this should be important, but not as important as that." And really, that's how it describes your documents.

This is very good because you can get very rich formatting with very little information. You're telling it to make it important, and then the browser decides how to make it important and how it compares to the other ones, versus sending across all this information to PostScript. But it's also a problem because it's very, very fuzzy. You don't have as precise control over how

your content is displayed, so there's a little bit of faith in each [inaudible] you have to have, and a little bit of faith in the browser, [inaudible] to render things appropriately because it's semantic.

Well, when you're dealing with a content conversion environment, what's going on is that you're converting from very literal market languages to a semantic market language, and you're losing resolution in the process. And that can be very problematic.

If you have questions about converting from [inaudible] into HTML... A quote that I had about that was that it's kind of like doing a great reproduction of the ceiling of the Sistine Chapel on a postage stamp with crayons; a lot of information and a lot of detail into something really fine. Yeah, it's a reproduction of the Sistine Chapel, but it doesn't really look quite the same because you're losing so much information. So you have to understand what is capable there and what to expect, and that can present problems for some of the content conversion environments.

Microsoft Internet Assistant is a plug-in to *Microsoft Word* which is free. It will allow you to save as HTML. The last time I used it, it still did a lot of things wrong, so be cautious with that. It does help out, but it can present problems.

What we're seeing now is more and more development on the service-side application. This is time for the shameless plug. We have two of these Netforms, and what that is is universal CGI script. What it does is eliminate the need to create a lot of custom CGI. Where you normally have to outsource or create internally, it automates that whole process. Or *Net Thread* — that is a thread-based discussion application, so you can do host-and-response discussion internally and externally and can provide a lot of power to a Web site. If you're interested more about those, I won't waste any more of your time here. Please do stop by our booth at the show.

There's more and more coming out on this. Some of it is very interesting, and some of it is very droll. But these are server-side applications, tools which compliment the Web server, ones that add sort of value-added features on top of it, but are not the Web server itself. What we're seeing is a steady migration towards that, which is meaning more competition for us as a company, but it is interesting. There are some good tools that are coming out.

Also, things that aren't on here. Very recent developments include things like Netscape's *LiveWire*. *LiveWire* is a complete document management tool and revision control system. They have announced it, but I'm not sure if they're going to be demonstrating it here. I'm not sure if it's fully ready or if it's vaporware. Things like that — there's a lot going on. It's good that this is all going on here.

For conclusion, in terms of the building of a site I went through the technical aspects and touched on some content considerations and the internal costs.

The conclusion for the buying I went through the general requirements, the costs of Internet consultants, and the costs associated.

Then finally for both, internal investment — what to invest in terms of capital equipment. What are you going to buy in terms of hardware? What do you already have available for hardware? What are you going to use for connectivity?

An issue in terms of this is that a lot of companies say, "Wow, it's a lot of money for this T-I if all I'm doing is putting a Web site on." But if you're installing a T-I or any sort of direct Internet connection, you can Internet-enable every single employee; have Internet on the desktop; have Internet e-mail, etcetera. This can open up a whole suite of possibilities for your corporation, of which having internal and external Web servers is only one of them. Also, what are you going to pay for in terms of human resources? Are you going to bring on extra people or are you going to retrain them? [You must also consider] the cost associated with external consultants for the different areas that you have consulted and whatever software tools you

choose to invest in.

Other information sources. If you need to get more, go to existing Web sites. The best place to find good info about the Web is the Web itself. There's a lot of good places out there, and it's also a good way to evaluate different vendors. There are other training sessions, whether they be seminars or giant conferences like this one. You'll see more and more in various metropolitan areas; full-day seminars being offered on anything — introduction to the Internet, advertising on the Internet, how to be a Webmaster, etcetera. Some of them are good, some of them are not so good.

That touches on magazines and journals. *Internet World* magazine and *WebWeek*, which are provided by Meckler, are both very good publications and worth reading.

Also related to that are books. There are millions and millions of Internet-related books out there right now. I caution you to be very, very careful in selecting them. What you'll see is a lot of Internet books which are this many screen shots and which are already out-of-date because their Home Pages haven't been updated from the time that they were published. Be a selective buyer in that.

Of course, I very highly recommend our book. If you want to see a copy of that, it's at our booth. It's a technical book there. What we have done, because we see a real lack in terms of very useful books on Web technology and there being a real need for that knowledge to get out, we actually just got involved with a four-book series deal with Wiley. So expect to see more and more books coming from net.Genesis in the future.

You could also pay for consulting services. We get a lot of requests — and we don't do it — to come in and train corporations. You can say, "You know, look, we want to pay for a day's worth of your time for you to come in and teach it to our people." And I'm not going to be very useful because what you can do is say, "Come teach to us, and these are the things we want to know." So you can very clearly up front specify that you want to know this sort of information and then make sure you get the most value for your time — as opposed to attending a general session like this one, which I'm sure had things that were useful and things that were not so useful.

WORLDWIDE WEB DOOMED TO FAILURE: UNSUCCESSFUL WEB SITES

MODERATOR

Kenneth Lane

WorldWide Web and On-line Information Consultant

SPEAKER

Jim Sterne

President, Target Marketing

Kenneth Lane: Good afternoon, ladies and gentlemen. Welcome to our first session of the afternoon. Mr. David Bunnell, who was supposed to be here to do this session, had a last-minute emergency and will not be here. However, we do have a very interesting speaker replacing Mr. Bunnell; his name is Jim Sterne, and I'll just give you a little bit of a background [on him].

Jim has spent over 15 years in sales and marketing of technical products. His unique brand of consulting focuses on product positioning and product presentation. Jim began his career helping people understand VisiCalc at a time when the personal computer was an oxymoron, and he successfully described sales-ordering processes to people using hand-cranked calculators. He was at the forefront of the computer-aided software engineering revolution, and has clarified the salient points of object-oriented programming. For the past two years, Mr. Sterne has devoted all of his attention to the Internet marketing medium. He has gathered information at conferences, on-line discussion groups, and from his own experience as a founding partner of a regional Internet access provider.

One year ago to this day, the National Center for Supercomputing Applications, NCSA, released the first public version of its graphical WorldWide Web browser, *Mosaic*. Target Marketing launched marketing on the Internet, as well as a seminar series — the first of its kind, an educational event which included five speakers and was delivered in five major cities.

Mr. Sterne stays active in a consulting capacity, helping each client set Internet marketing goals and determining strategies. He offers unique creativity in the design of an on-line corporate presence, with an eye towards engaging the viewer.

Just as a little addendum here... Mr. Sterne also has a new book which was just released by Wiley & Son, called *WorldWide Web Marketing: Integrating the Internet Into Your Marketing Strategy*. I believe Wiley & Son is here, and you may be able to pick up a copy at their booth.

Without further ado, Jim Sterne.

Jim Sterne: Thank you very much. When I was called on Thursday and asked if I could provide a presentation on this topic, I thought, "Doomed to Failure!" But here I am anyway.

It's a great subject to think about, because we're all nervous about getting out there, putting ourselves out in a publishing position out on the WorldWide Web and being afraid that we will be doomed to failure. So I'm going to try to provide a couple of pointers to show you what not to do, and to help you have a presence that is a corporate asset instead of a corporate embarrassment.

Here are the five issues. These are the top five ones, and I want to go through each one of them specifically: not putting together proper goals; not putting together proper plans; not taking advantage of this fabulous technology; insufficiently promoting your site; and not focusing on the fact — the main point, the big deal — [that] this is a communication medium, not a broadcast medium.

So, what's an unrealistic goal out on the Internet? There has been a lot of hype, and

those of you who heard the keynote speech this morning heard the question [that] maybe we are under-hyping it. Well, maybe; but for the most part those of us who have seen the ads and heard the radio commercials for the \$29 seminars — where you don't need any computer experience, you don't even need a computer, you can make money fast on the Internet — we're a little nervous about the hype.

These are unrealistic goals. It's unrealistic to expect that you can simply broadcast your message out to 50 million Internet users. It is not a virgin, untapped market; it's a bunch of people whom you are already reaching through newspapers and television and direct mail. Now you [only] have a new channel for each of them — so they're not new, they're not untapped. They're segmented — that's [a] good [term]. But you're not going to reach everybody all at once.

[The Internet] is not going to let you give up on all the other forms of marketing that you do. It's not going to let you say, "gee, we can stop doing direct mail, we'll publish once on the Internet, and everybody can see it." No — it's in addition to. That means, yes, you have to dig in your pocket and come up with more marketing dollars to support this thing.

It doesn't sell product automatically, or "automagically," as I put it here. You're going to have to use common sense, good marketing skills, and good sales skills just like you do in any other medium; but you need some new skills for this one.

You are going to make money on the Internet. You're not going to do it fast. But the real issue here is that the growth is so exponential, and the opportunities that are available are growing so exponentially, that there is a niche somewhere for each and every one of you — especially because you have to stop and realize that this is the early days. This is new; this is at the time when people used to take their newspaper pictures and their radio copy and put that [together] and call that television. There's a lot we can do on the Internet that we haven't even guessed about yet.

The Internet is not a replacement — you're going to have to do all of your normal marketing anyway. It's not stand-alone. You need to do this sort of work on the WorldWide Web in conjunction with the rest of your marketing. You have to tie it in with the rest of your corporate message. You have to tie it in with the events that you're doing, the sales that you're offering, the general marketing that you do, [and then] make sure that the Web is part of it, not separate from it.

The Internet is not a place full of people who are ready to buy anything that comes along. These are not people who are just sitting around with money in their pockets; these are very intelligent users, and you have to treat them intellectually.

And finally — and most importantly — it's not a broadcast medium. Television lets you broadcast a message. Now, what does that mean? Right now I'm broadcasting to this audience; you're sitting in the audience, you're in listening mode, you're letting my words wash over you. Hopefully every now and then one of them will stick, but you're receiving. On the Internet, on a Web site, you interact, and you're taking part in what I present on a Web site. It's an important difference.

There are a handful of realistic goals that you can put together into your marketing plan. It is definitely possible today, with today's technology, today's audience, today's Internet, to sharpen your corporate image. It used to be that you get a Web site up on the Internet, and boy, and you were cutting-edge — you're a leading-edge company, you know what's going on. Today we're at that place where, if you have a Web site, that's pretty neat. Tomorrow, if you don't have a Web site, you will be conspicuous by your absence. "You mean you don't have a fax number? You don't have voice mail?" It's going to happen very quickly. So you can sharpen your corporate image today by getting a Web site, and keep from tarnishing it tomorrow.

Improving customer service... That's probably what makes my heart flutter when I look

at the Internet. The ability to allow your customers to reach into your company and help themselves is fabulous. It's tremendous. We've never had an opportunity like this since the dawn of the 800 number; inviting people to come in and answer their questions, give us their opinions, and become part of our corporate family — the bonding with the customer.

[There's a chance for] heightened brand awareness, certainly, and to qualify prospects, definitely. Those of you who have technical products, long sales cycles — your sales people spend more time in education than anything else. Get the Web site running. Your prospects can come and teach themselves at their own pace and their own time, when they're ready to receive the message, and your sales people can spend their quality hours, their expensive hours, on-line closing the sales.

And of course we want revenue to increase, so yes, you can sell products. You're not going to make a million. You're going to put up a Web site, and people are not going to rush to it and buy things from you just because it's there.

You have to be very marketing-savvy about what your Web site looks like, and how it acts and how people interact with it. It's creating that open, electronic dialogue with people that's going to hook them, excite them, keep them at your site and get them to come back.

Another thing that dooms a corporate Web site to failure is the lack of planning — the, "Hey, let's put up a Web site! Let's put up a Web site, and it doesn't matter if it's under construction, everybody knows that everything is just fast and loose on the Internet..." When was the last time you created an eight-page, four-color brochure and the last two pages were blank? Don't do that! Don't do that on the Web. Don't make it under construction. Don't offer something, "click here for good information," and they click on it and it says, "come back next time." Don't do that, [it's] bad marketing.

You need to plan several different stages. First of all, what's the front-end going to look like? What is it that the person is going to see? You have an opportunity to create a graphically-rich, media-rich environment, but you have to do it carefully and consciously because we don't want to overload people's 14.4, and now 28.8, modems.

And just as you have to do graphics carefully, you have to write your copy even more carefully. The studies have shown that people read faster, with less retention, and are less inclined to read a lot of text [when it's] on a computer screen. They want the information quickly. So they're going to read 50% less, and you better write 50% less. Make it short and to the point, so that people have the opportunity to drill down to where they want to.

Don't give them a Home Page that has your whole corporate story on it. Give them an opportunity to learn on their own, by digging. That doesn't mean make a thin Web site; make it deep, but don't put everything up on the top layer.

Professional layout is going to allow people to access your information. If it's got a nice format to it and it's easy to understand, people will use it, come back, and be delighted to be there. You also, for the front-end, need to think about what your map is going to look like. How deep does your Web site go, and in what areas? Well, there's what I call the usual suspects.

You go to anybody's Home Page, and you'll find "About the Company," "The People at the Company," "About Our Industry," "What's New," and "Our Products." Now, when a visitor comes to your Web site, and they see "About the Company," and the mission, the history, the different divisions, and the charity work you do, it's almost as if that area of the screen is invisible. Nobody cares what your corporate mission is. People are sort of interested in people, so they'll go to your contacts area to see how to get in touch with the right person. They're interested in your white papers; if you're putting together an offering of information, for free, about what you think is going on in your industry, people will read that. They're interested in your perspective, because frankly you know more about your industry than they

do. You're a source of information that's useful to them.

The "What's New." If you put up the "What's New" bug and let people click on it, they will go there. People are curious; they want to find out what's the latest and greatest.

But by far the most often visited place on anybody's Web site is "Products." People are not there to win prizes, and they're not there to see your nifty graphics; they're there to learn more about your products while they're making a buying decision. Make that area deep, and plan your map. Sit down and do the usability study, so that you can tell, "is this the logical place to put that information, and are we presenting it in the correct order?"

You're also going to need to work on planning the back-end. On the back-end, you've got data collection happening. People are coming to your Web site and logging in and reading about your company; but you know that it's an interactive medium, so you're creating forms and you're collecting information about them.

What do you do with that information? How does that flow through your data collection system? How is it stored in your database? What else are you going to do with that database? Work out the flow chart, and work out the database design so that you know ahead of time what questions you are going to ask of that database as you start collecting the answers.

Finally, [I want to talk about] the ties to the corporate systems. Federal Express is probably the first one out there that really provided end-user access directly to their corporate database. "Where is my package at this moment in time, when was it delivered, who signed for it?" That's reaching into the glass house, that's opening up the corporate data center to the Internet. People are going to expect that more and more. That takes some very careful planning, some serious planning, some security planning.

Well, all of this sounds like it's going to take more than \$50 a month to hack together an HTML page, so maybe we ought to worry about the resources, and we ought to plan on what we're going to spend.

We're going to have to hook up to the Internet somehow. Yes, you can buy a \$50-a-month Web page; yes, you can spend several million dollars on your Web site. We've seen both examples. Getting connected to the Internet can be easy and quick; or you might need a large connection, in which case you're dealing with telephone companies, [which are] not known for turning on a dime. Plan for that. You need to plan the hardware that you're going to provide, which is dramatically inexpensive; a very nice Sun workstation, a very nice Silicon Graphics machine, a very powerful Hewlett-Packard machine, and for \$15,000 to \$20,000 you can have a very nice Web server. But you better find someone who is going to come up with the budget for that. There's also some software you'll need to do, and you'll also need to think about the people [you'll need].

Now, the people that are needed are a really interesting category, because there is nobody that has five years' experience creating Web sites, so you really have to judge talent. You really have to go to your competitor and steal their top people, because there are very few folks.

In fact, I was reading in — I think *TIME* magazine — [which] said that right out of college [there are] people who have HTML experience, are UNIX savvy, and understand a Web site, and are garnering \$90,000 to \$110,000 right out of the box. Three years from now that won't happen any more, because there will be enough people who can do that, and enough tools so that the rest of us can do it. But today they're expensive. Plan on it; expect it.

The kinds of people you need... Somebody has to create content. Somewhere in your product organization — the product marketing manager, the product development manager — somebody there knows enough about your product to know what information is necessary, what order to put the information in, and [then] deliver it and say, "okay, put this up on the server." Before it goes on the server, though, it better go through the filter, [to check for] the

corporate communications, the corporate identification, the corporate logo, the corporate color — the filter that says this is the style that we use in this company.

Now, once it gets through that filter, it can go to your technical staff, who are the servers. This is our technical server. Your technical people are going to have to be network-savvy, they're going to have to be Web-server-savvy, and they're going to have to understand how to work with end-users, in this case the marketing department. Plan on having a group of people from all over the organization who are going to work together as a team. There is no organization within your company that can do this alone; it's a team effort.

When we talk money, we also have to talk time. For some companies, this is a time-line in weeks, this getting your strategy together and planning out your implementation. [Then] there's a three-week fight over who owns your Web site. Does it belong to IT, does it belong to marketing, does it belong to corporate communications, does it belong to your PR agency? You better plan some time to work that one out.

Access is a long process, because again that's out of your control. You're waiting for the phone company or your Internet access provider to show up with a T-1 in hand. That doesn't happen instantly.

[So you're] designing, prototyping, and then right away you'll want to start creating content and validating that content from a marketing perspective and a technical perspective. In other words, if you give me a picture of the product, can I properly put it into a form that can be seen on the Web?

And then testing, testing, testing.

Those are processes that will continue forever; and just when you think you've got [things] organized, it's time to look at your strategy and your planning [again], because this world moves fast.

Another way that Web sites are doomed to failure is by not utilizing the technology that we have. This is the dirty little secret about publishing things on the Internet: that it's a lot of fun. It is. It doesn't take much to do a little HTML and throw it up on the Web — and look, everybody can see it! Well, the problem is that if you don't put enough technology out there, you end up with some problems.

I decided to pick on the National Business Incubation Association. I hope there's nobody here from that association today... Good. [This one's] doomed to failure. Folks, [let's say] there is a graphic [you designed]. It's probably a beautiful logo. [But what if] we can't see it, or you named it wrong? Fix that! [What if] it's a spelling mistake in your brochure? Don't let it go out the door.

They have a list of members in alphabetical order, which is very useful for those of you who know the name of the company that you're looking for. If you're looking for a particular type of technology, you get to click on each one of those to find it; [though a] little bit more organization would be helpful.

Well, let's go visit some of these. Let's start up in Canada. Now, the Canadians decided to do a text page; they didn't quite want to get to the graphics or the layout, or the enhanced-for-Netscape stuff, but they gave us a link. Isn't that nice? There's a blue spot, and we can go and press that button.

When people come to your Web site, they're not there to read about you, they're there to find out what they can do. They want to know what buttons they can push. Here's a Web site — what can I do? Where's the blue spots? [You need] one blue spot — it's great from the control perspective.

Here's a company that said, "ah, out in Long Island? We can pick up a picture. Let's put up a picture of something that everybody wants to see — our building!"

The Boulder Technology Incubator said, "oh, we know how to make the background

white.” They get three points.

High Technology of Rochester said, “oh, we know how to put in a colored background.” Pretty nifty Netscapism.

These people have a banner up at the top. That’s pretty good... Their logo is there, [and it’s] pretty catchy. And look, bullet points. Three-dimensional bullet points — these people are really getting sophisticated.

Ah, a colored background. These people actually took a picture and made it into tiles; boy, that’s enhanced for Netscape. That’s terrific.

There was one place in that list that had an interesting-looking Web site. It’s in Germany. They figured out Netscape, how to label things, [how to create] nice graphics; at the bottom [they had] a Netscape I.I, enhanced for maximum viewing pleasure. The country that gave us Fahrvergnuegen now gives us Surfvergnuegen.

This was my favorite of all of them — this belongs in the *New Yorker* magazine’s “Web Sites We Never Finished Reading.” [It’s the] Technology Development Center Fact Sheet. Who are we? I don’t care!

I went to *Yahoo*, and when I searched for Incubator I came up with the all-time worst Web site. Don’t ever, ever, ever do this. This first one is the NASA Johnson Technology Communications Center. 404... File not found. Shame! All right, also doomed to failure.

If you over-utilize... We all love to pick on *Hot Wired* magazine; who am I to differ? Actually, this is pretty well laid out. It’s a little bit difficult to read — I admit to being over 40 — but at least it’s not as bad as hyper-fuzzy. You know that when you go to the enhanced-for-Netscape Hall of Shame, and their number one pick is hyper-fuzzy, it’s a great example of what not to do. If anybody can figure out what this site is about, and what it stands for, and what those buttons are, send me some e-mail, will you?

Insufficient promotion is one of the largest things that will doom a Web site to failure. If you don’t let people know it’s there, they won’t know it’s there. You can go out and announce this thing, this new Web site or new additions to your Web site, in on-topic, specific newsgroups, in [the category] “Announce Newsgroups and Web Sites.” But many, many words of caution — well, a big caution — [use] few words. Do it carefully!

If you’re going to go to a newsgroup and announce that you have a commercial Web site available, you better be familiar with that newsgroup. You better have read their introduction; you better have read their “Frequently Asked Questions.” And you really ought to have hung out there for a couple of weeks and read the posts to know what the local culture is. We’re not talking general netiquette or general culture; we’re talking very local, specific newsgroup culture. If you do that wrong, it will hurt you a lot more than if you don’t announce at all.

There’s also some help you can get in announcing your Web site. This is a company, Submit It, [where] you tell them the description of your site, and boom, they send it out to dozens, soon-to-be-hundreds, of different “What’s New” pages.

There’s another one called *Postmaster* that does the same thing. There’s another company called Netpost, [at] netpost@netpost.com. [Eric Word] does it very personally. These are automatic systems; you type in the descriptions, and it forwards them. [It] saves a lot of time, but doesn’t tune it. [Eric Word] will go out and tune your message to the right list, to the right newsgroup, so you can farm out this activity.

You can also buy links. You want to take your little logo and sprinkle it around the Internet? Great, open your wallet. Netscape is charging \$14,000 a month; *Hot Wired*, fifteen; Prodigy, sixteen; and NCSA will only cost you \$30,000 a month to advertise on their page.

This morning I talked to Glen Davis, who runs the “What’s Cool: Cool Site of the Day.” He now is very pleased to say that he has the highest per-thousand-dollar value for advertising.

He started taking advertising three weeks ago, and there has been a bidding war for space on Cool Site of the Day. Get your bid in early, and bid often.

Also, [about leaving] your [electronic Web site] signature... Now, I'm assuming that some of you have outside activities [other] than work — I think there may be two of you out there today. If you post things to alt.recreation.bicycles.racing, it's okay on the bottom to have a couple of lines that say, "by the way, we make the best bicycle tires on the planet, check out our Web site."

In fact, if you post to rec.pets.dogs.health to find out how to cure your dog's fleas, you should put, "we make the best bicycle tires on the planet," and [list] your Web site. Why? Because a signature is okay. The message above the signature has value; the signature itself is innocuous. But it clues people in that there is something else to go look at.

Why is it important to make sure that that's in an off-topic newsgroup? Because *Deja News*, and *InfoSeek*, and *Yahoo* and *OpenText* are going to be able to scan those. So when I go look for bicycle tires, I'll get this posting about some guy who is worried about his dog's fleas. "Oh, look at the signature. Bicycle tires; that's what I was looking for." It's a way of getting your keywords out on the Internet.

Keywords also belong on your Home Page. Let's say you sell shoes. Shoes, sandals, Bostonians, slippers; there's a lot of words for shoes. And if I type in "hiking boots" and you don't have hiking boots on your Home Page, I don't see it. How do you get hiking boots on your Home Page?

Well, programmers know that there is something called "the comment." The comment in your HTML is a piece of text that is not seen by the viewer; the browser ignores it. So you can have a long list of keywords that are commented out, [but are] still there; and when the spiders come — *WebCrawler*, *Lycos*, *Yahoo* — when they come to look, they'll see those keywords, and they'll store them in their database and people will be able to find you easier.

And [then there's] traditional marketing; I can't stress it enough. Go out there and market as you would anything else. If you have a 1-800 number and you don't tell anybody, you won't get any calls. Make noise out there, through direct mail, on TV and the radio, that, hey, folks, we're now available through the Internet at www.company.com.

This last item is one that I think we're going to see more and more and more and more and more. The reason that people get on the Internet [is because] you're supplying some value-add that is interesting enough and sufficient enough that somebody is going to say, "you know, okay, I'll get on-line so I can have that." They'll say, "I'm willing to finally take this 493rd America Online diskette that has shown up in my mailbox," or "I'm willing to take this diskette that I find in the glove compartment of any Volkswagen," — [because even] they're shipping them now — "put it in my computer, and it will take me on-line, it will give me seven days of free access to the Internet..." And it will take me directly to the Volkswagen Home Page.

CompuServe now has a service where they will brand your own browser for you, stamp it into a CD, and allow you to mail it out to all of you your customers.

Now, if you have something that is compelling, that is valuable, that is content-rich and interactive and really provides a service and helps somebody get their job done — not just selling T-shirts, but actually helping somebody in their day-to-day tasks — they're going to say, "oh, I can access company.com, and I will." Not, "ooh, I want to surf the Internet, man."

No, [that's not what they want]. "I want to contact that company, and do that transaction." Or, "I will use this diskette to contact Federal Express so I can track my packages, because I'm the shipping manager, and that's what I do for a living and it's worthwhile." [And then], "oh, by the way, I now have access to all the rest of this Internet stuff." Your job is to think of what you can provide that is valuable enough and interesting enough to compel people to get on-line. Let all this surfing take care of itself.

The last one that will doom a Web site to failure is the “Company Publish” model. Company Publish says, “look, we’re on the Internet, isn’t this cool. We have a Web site, aren’t we great. Learn about our company, learn about our CEO. Oh, by the way, we have some product stuff over here, but, oh, look at our new building. Oh, meet our head of human resources...”

People don’t care about that. Some people are interested in your annual report, but not everybody. They’re interested in your products. Although I have to admit, there is a time where it’s important to put your CEO on there. John Patrick, who is head of the IBM Web Initiative, tells the story about going into Lou Gerstner’s office and saying, “look, this is the WorldWide Web, isn’t it neat?” And Lou says, “well, yes, that is pretty neat.” And [then John Patrick says], “and seeing that we have a picture of you, we want you to be on our Web site.” “Oh, gee, that’s very neat,” [Gerstner answers]. “And Lou, we want you to speak this little speech into this microphone right now — ‘Hello, I’m Lou Gerstner; welcome to the IBM Web site’...”

The next day there was an all-manager IBM meeting, at which they gave a demonstration of what would be IBM’s Web site — including a big picture of Lou Gerstner saying, “we’re going to be a leading force in the Internet industry.” [It was] amazing how quickly they got all of those managers from IBM on board, just like that. So sometimes there’s a reason to have your CEO on your Web site.

The fact is that the Internet is giving us access to our trading partners like we never had before. Customers want access to information about your products; they also want access to information about the process. “Where is my shipping order? How long is it going to be back-ordered? If I change the color to green, can I have it tomorrow?” They’re going to want to get involved in your policies, they’re going to want to get into your management’s heads, and they will have the power to respond to you directly and instantly. They are going to expect to have access to your company; prepare for that.

If all you do is put up a brochure, you’re not going to make it. It’s your responsibility to focus on customer service, to focus on the interaction, and to remember that this is not your brochure, this is your customer’s experience. It’s them sitting in front of the terminal, saying, “what do I want?” not “what does the company want to tell me?”

So pay attention to these things, or you too can be: “Doomed to Failure.” Thank you very much. And we have some time for questions.

M: [inaudible]

Jim Sterne: Is all this stuff on my Web site? By the end of the week it will be, yes.

M: [inaudible]

Jim Sterne: Have I seen Mirsky? You know, I really wanted to spend about two days... People should know there’s something called “Mirsky’s Worst of the Web,” and it is a little more entertaining than the Enhanced for Netscape Hall of Shame. Well worth the time, to learn what not to do. Thank you. Any other questions?

W: [inaudible]

Jim Sterne: The question is [about] using keywords on your Web site; if you haven’t done it yet, is it too late? No, it’s not too late, because the *WebCrawlers* and the *Lycoses*, their job is to go out over the Net all the time, because Web sites change on a minute-by-minute basis. They’re not going to survive if they take a picture of the Net this Thursday and it still looks the same

next Thursday. So go ahead and do it now, it's not too late. Any other questions? Yes.

M: [inaudible]

Jim Sterne: The comment is that all of these graduate students are coming in, and they have a lot of Web knowledge and UNIX knowledge — that's terrific, they need them — but they don't have the business knowledge. The solution for that is teams. You need to have the young, excited, live-on-pizza-and-Jolt-cola folks to do the work and understand it.

By the way, find somebody in your company who is willing to have as part of their job description Web surfing, to go out there and look. I mean, people in your marketing department go to a trade show; what's the one most important thing they do, besides meeting with the press and trying to sell your product? It's collecting brochures from everybody else in your industry so you can see what they're up to.

Do that on the Web. Create a team of people that has the Web surfers, the young, talented techno-geeks and the gray-haired, business-savvy folks, and force them to learn to get along together. If they do it successfully, it's going to be "Not Doomed to Failure." Any other questions?

M: [inaudible]

Jim Sterne: The comment is that your corporate library may be out there doing research for you already that you don't know about. This is a key point. Your corporate library probably is staffed with people who have doctorates and advanced degrees in library science; these people are golden. They can find things.

When the CEO comes down and says "I need a competitive analysis by 3:00 this afternoon," go to the people with the library science experience; you'll be amazed what they can do. Good comment, thanks. Yes.

W: [inaudible]

Jim Sterne: What's my most compelling reason, when I talk to my customers, about why she should not put the CEO, and the building and the mission statement up on the Web?

Diplomatically? The most compelling reason is that it does not further the strategic goal of having a Web site. Number one, first thing out of the box — why do you want a Web site? "We want to accomplish this." Explain to me how a picture of your CEO is going to accomplish that, and I'll buy in. Otherwise, I don't see it.

M: [inaudible]

Jim Sterne: The question is how do you convince a hundred-year-old, department-store kind of a company that is focused on profits and on selling that this is a different paradigm, and that you have a communications problem to deal with instead of a salesmanship problem? Well, obviously, John, the answer is — hire a consultant!

It takes a lot of convincing. It is a new thing; it's different. But probably the most compelling way to do it is to find a Web site that you think has done a real good job, and put your management in front of them, or put your management behind the seat of somebody else who is visiting that Web site, and let them experience what happens to somebody when they really interact instead of just reading [something] or getting sold to.

The fuel to the fire here is [the attitude], "gee, nobody is making any money on the

Internet,” so the managers and the VP’s are disinclined to put any resources into it. I would say that that was last year’s news. Starting January 1, 1996, I don’t think you’re going to be hearing people crying that any more, because we are learning how, and we are successfully selling more, so that it offsets the costs, and we are saving money on customer service, which [also] offsets the cost.

We have time for one more question.

M: [inaudible]

Jim Sterne: How would I modify this model for nonprofits? A nonprofit is in the business of solving a social issue. That makes you the key source of information about that issue. If you become the resource, the electronic resource, of that information, it will attract people to your site. Then, I’d say to go to the commercial world and do the tie-ins, just like on TV during pledge week, “here’s a book you can have if you pledge so much, here’s a tote bag you can have if you pledge so much,” and get commercial on it.

Thank you all very much.

WORLDWIDE WEB THE TRIALS AND PITFALLS OF BUILDING A WEB SITE IN A CORPORATE ENVIRONMENT

SPEAKER

Kenneth D. Lane

WorldWide Web and On-line Information Consultant

Kenneth D. Lane: Good afternoon, ladies and gentlemen, and welcome to the second of this afternoon's sessions, which is going to deal with the trials and pitfalls of building a WorldWide Web site in a corporate environment.

This session will cover the planning, design and development stages of building a WorldWide Web site, and how these issues need to address the politics and culture of the corporation — that is, the importance of getting the organization's key players to buy into the plan. During this session I hope to answer some of your questions; but more importantly, I hope to be as provocative as possible so that you will begin asking questions, and hopefully arrive at conclusions by answering many of these questions on your own.

This will be an interactive multimedia presentation; by that I mean that you will be able to see me and hear me. It's also going to be interactive because we will have questions and answers.

The format will be about 40 to 45 minutes of presentation, and at the end we'll have about 15 minutes for questions and answers.

Just as a reminder, for those of you that are trying to take notes, there will be an audio tape available of not only this but all the presentations, and at the very end of the conference there will be a CD available with the entire proceedings from the entire conference.

(Plane flying over)

Murphy's law. I will be talking about Mr. Murphy quite a bit this afternoon. Information about those items can be found up by the registration area, for those of you that have some immediate interest.

In many corporate environments there are probably competing or diverse divisions, some of whom are very Web-savvy, most of whom are not; some with over-inflated opinions or exaggerated notions about what the Web will do for your company, and some with very realistic expectations.

So, let's meet this first issue head on. Just what are your reasons and expectations for building a WorldWide Web site? This may seem like a no-brainer for some of you. The competition is there; we want to use the Web as a marketing tool; we want to save money; we want to conduct business over the Internet; we want to be philanthropic.

All good, sound reasons for wanting to build a Web site; and for those of you who are not sure, let me share with you some recent demographic information gathered by *Yahoo* at Stanford University in a recent survey.

For those of you who may not be familiar with *Yahoo*, *Yahoo* is probably one of the best sources for locating information about sites on the Web. At last count, there were over 30,000 links to sites that you will probably want to check out.

Of course, there are a number of other site locators, such as commercial services on the Web, *WebCrawler* and others that you will also probably — if you haven't already — want to explore.

Copies of the *Yahoo* survey can be found right up here afterwards if you want a copy to take back and stick under someone's nose. They are available here, as well as on their site.

If anyone is interested in participating in another survey, if any one of you are participating in another survey that they're about to begin, you can e-mail them at survey@yahoo.com.

In terms of demographics, here is how the questions were answered. Each percentage is based on the total number of people who answered that particular question; and I might add that 67,000 responses were received as part of this survey in less than a week's time.

The first question was, in what part of the world do you live? The USA came in at number one, at 76.4%; and then it starts narrowing down. Canada was next at 8.6, the UK at 2.9, and so on.

So as you can see, your primary ADI, or "area of dominant influence," is in fact here in the U.S.; but don't overlook some opportunities abroad.

Are you male or female? Male response, 83%; female response, 17%. First pitfall — don't fall into the trap of being misled by this, or any other single source of market research based on this kind of response. If you were to evaluate the male/female ratio of connectivity to what we in the industry call "primary on-line services" — services such as CompuServe, America Online, and Prodigy, as well as the professional on-line database services such as Knight-Ridder Information Services, Lexis-Nexis, DataTimes, and a number of others — you will find that the number of females is going to be closer to 50-50. In some cases possibly 55-56% of your on-line audience is in fact female, so you don't want to overlook this potential in the market.

How old are you? Less than eighteen, 7% — there goes Al Gore's theory, right out the window. Eighteen to 35 years, 54%. Thirty-six to 54, 34%. Fifty-five and older, 5%.

This demo, by and large, is very impressive and holds fairly consistent with a lot of other data that I have seen. Why? Because most companies who market and advertise in mainstream media try with all their heart and soul, activities and dollars, to reach this market.

For example, the 18-35 age group represents purchases of durable goods, automobiles, homes, the big-ticket items. The 36-54 age group represents a higher level of disposable income — the adult-toy market, if you will — the expensive computer, cellular telephones, in-home theaters, dining out, expensive vacations, and other such discretionary income spending.

What is the highest level of formal education you have completed? Grade 12 or less, 7%. High school, 22%. Bachelor's degrees, 37%. Graduate degrees, 27%. Others, doctorate and above, 7%. This is a well educated, knowledgeable group, so don't talk down to your audience. Enough said!

What is the marital status? Single, 54%; married, 46%. Inconsequential? Maybe, maybe not. This almost 50% statistic may provide opportunity for some vendors who have goods and services that appeal to either or both of these audiences.

What is your current profession? Managerial/professional, 42%. Students, 23%. Technical, 19%. Academic, 8%. All others, 8%. Obviously it's a large segment of professionals who are making or who are influencing buying decisions.

What speed is your primary Internet connection? Less than 14.4, 6%. 14.4 and above, 44%. 28.8, 17%. 28.8 to one meg, 10%. One meg and higher, 8%. Others, 2%. 13% didn't know how fast they were going.

These statistics can also be a bit misleading. Although many of these individuals surveyed may have had home modems that operate at those speeds, if they are using on-line services such as CompuServe, America Online or Prodigy, the best connect that they're going to get right now is 14.4, if they're lucky. More than likely, 19.2 is the highest rate of speed that those services are providing at this point in time; tomorrow it may be a whole different picture. So here's a good reason why design is very important.

The speed at which most users surf the Net is, in fact, one of the most important issues in your first elements of design. Don't use gigantic graphics, or colossal graphics and maps that fill the entire screen, or even too many graphics that might look impressive to you and your art department and all your people inside. If they take too long to download, you'll frustrate any visitor that comes to the site, and more than likely they won't come back.

And I want to share with you a little story. When I was looking for some information on the Web personally, I happened to visit a publisher's site, and zeroed in on a particular title that I had some interest in.

On the first page-level down from their Home Page, in getting that information, there was a photograph of the author which took up about 25% of my screen. So I waited and waited and waited, and it was a bio on the author, very nice. At the bottom of the page it had a link to some of the information that I was looking for: table of contents, preface, bibliographic information and such.

I go to the next page; the same photo starts unwinding on my screen. I'm waiting and waiting and waiting; got to the next level, and the photo is there again.

I rarely send hate mail to anyone; in this case, I did. Sometimes I write it and don't mail it, but in this case I shot off a letter and e-mailed it to the publisher, and shared my view.

Now, having done some writing myself, I know authors have big egos, and they love to have their picture out there and they love that you know all about them. However, as a user, I don't need to see that photograph three or four times. So keep this in mind when you're in your development stage.

The next question was, what is your level of Net experience? Beginner, 27%. Intermediate, 52%; advanced, 21% — whatever the hell that means, "advanced." I'm sure these people may have started a good many years ago, when there were just Gopher sites around and you had to navigate through some sort of special coding on a UNIX platform. This, in today's market, is obviously no big issue.

But one thing you want to do is to make your site easy to navigate and as interesting as possible. Use menus with hot links, so that they can go logically from level to level. And you want to take your visitor on a tour using these links.

Some of you might even want to consider a "search entry" if you're going to put up a lot of content. If you're going to plan ahead for your database up there that's going to have all kinds of information in it, you want these people to be able to get to your information as quickly as possible.

How many hours a week do you typically spend on-line? That was the last and final question, I believe. Zero to five hours, 28%. Five to 20 hours, 55%. More than 20 hours, 17%. So we're dealing with a group of people who obviously spend a lot of time on-line compared to traditional on-line services such as CompuServe and AOL and the like. These numbers are quite impressive.

This is probably one area that's going to increase more rapidly than the other categories, because as connectivity providers with increased service, more nodes, more connectivity, and then even more providers come on the scene at a more competitive price, you will see vast numbers of increases in this service, because obviously — my phone bill last month was about eight hundred bucks, most of which was on-line time.

So as this price structure becomes a little bit more manageable for most people, they will be spending more time on-line. And if they're newbies, they're certainly going to spend a lot of time. They're like children with new toys. "Oh, look, mom, I can do this." And the wife is leaning over and says, "Hmm, that's nice."

So now we have some hard data at this point that might provide some insight about who uses the Web, and why you might want to reach your market via the Web. But before you

start chasing your tail, or before everyone in the company starts chasing your tail — some of whom may even want to bite it off, or some other area of your anatomy — it's incumbent upon anyone who is considering building a Web site, or who may have one under construction, especially those of you that are committed and are in the line of fire, that there is a clearly defined mission that covers all the right and realistic reasons for building a Web site in the first place.

Now, for those of you that were here for the last session, I may be echoing some of this all over again; and if we are of one mind in sharing the same intellectual consensus, then there's got to be some validity to this.

Over time, your mission might, of course, change, expand or contract depending upon your company's situation; but you certainly will want to start from that perspective, and also address such issues as expectations versus realities while you're at it.

With the diversity of opinion in most corporate settings, it might be a good idea to bring all the departments or divisions together for a meeting of the minds, to hammer out this vision of your mission. The group should include division heads, department managers, your systems people; anyone that might be involved not only in the design, concept and staging of your initial Home Page, but the on-going process as well. [Also] information managers — the librarians that Jim spoke about a little earlier. So, anyone and everyone who will be involved with that process at any stage of the game should be in on these early meetings.

You might want to follow these basic steps to “operationalize” your mission statement. Craft the statement that answers three basic questions.

What business activities will we be involved in down the road, in say, one, three, and five years? We are talking a long-term commitment here; in most cases, to sell this to management in terms of resources to build a Web site is going to be difficult to do, because you're not going to see that kind of return immediately. So you really have to look at the big picture in long terms.

[Second,] what are our objectives, and [third,] how will we reach our goals?

Once you have established the answers to these you need to communicate this mission throughout the entire — and I mean the entire — organization, down to the receptionist. That individual has to know, if a customer calls and inquires about your Web site; that individual should be at least in a position to give them your address, and to know that you have a site available; not something like, “Oh, we have a Web site? What's a Web site?” You certainly don't want that to happen when a customer or a potential vendor or a partner may be on the line inquiring.

Then you need to translate key elements of this position into relevant performance objectives, for employees at all levels. Typically, a statement might read something like this: “The primary mission of, quote” — let's call it the on-line services department — “is to enhance and expand the capabilities of such-and-such divisions to acquire, develop and market products electronically.” This could be the bare-bones core of your mission statement.

Then you need to take that a level down. “Through innovative uses of the Internet, and other related on-line services” — which we may become involved in later on — “we will reduce costs by providing low-cost electronic access to marketing and other information, supplemental software, tools, etc.,” whatever it is that you're going to be giving away.

Teaching aids accelerate the integration of the Internet marketing and electronic publishing techniques into your acquisition, marketing, and distribution process; provide a testing and marketing research platform that will help to gauge the market for fee-based electronic products and services, and promote the acceptance of on-line electronic technologies as a marketing and distribution vehicle amongst the divisions or sales organizations within the company.

Now, that typically addresses a lot of issues, and of course I'm using an example from a publishing industry, which may not suit your particular purpose. However, it gives you some focus as to some of the major points that you need to develop as part of this mission.

Once realistic agreement on mission is established, one that will meet the needs, interests and desires of the company as a whole, only then should you embark on this venture; and hopefully it will not be as perilous as those of you who have jumped in the water without doing this first.

Now, here's where documentation is going to play a very important role. Always, and I mean always, document every meeting and functional activity; then copy everyone that was there. If someone for one reason or another was not there at a particular meeting, make damn sure that they get a copy of what went on at that meeting. And do this for every functional meeting, especially where concepts, tasks, or time-lines are discussed. If there are some misunderstandings, that documentation will help to clarify it. If there is some disagreement about what was discussed, the documentation will initiate additional dialogue and give additional clarification.

You don't want to fall into the trap of verbalizing anything of importance. For example, a verbal statement such as, and I quote, "I think I, or the team, can have this for your department by next Wednesday," then adding, "barring any unforeseen circumstances, of course," which is almost a throw-away. This statement, if communicated verbally, will be carved in stone, and you will be expected to have that task completed by Wednesday. Inevitably, the person or group you made the statement to will not have remembered hearing the last part of your statement, "barring any unforeseen circumstances."

But when you put "unforeseen circumstances" in writing, you allow for a little latitude. I might suggest that you will need that latitude. If you think you can have it by Wednesday, tell them Friday, or maybe even Monday; when you deliver by Wednesday, you will certainly be a hero. If you can't deliver by Wednesday, you've got a couple of days to play with. Time is on your side, and this is going to be your absolute worst enemy.

So don't paint yourselves into a corner. This is just good common practice to get into, especially in an environment where you may be dependent on the mercy or the performance of others who you may not have any control over.

This is a safe and sane technique to use in almost any situation in which the final outcome resides at your doorstep. You don't want to lose face, and worst of all, you do not want to lose credibility, especially at the early stages of this game.

It would probably be a good idea to recruit, invite, or have one or two individuals from each division or department assigned to participate in the project. If you get this kind of cooperation during the early stage, you know that you're now starting to get some buy-in. Then, as delegates from the various divisions become more involved in the planning and development of your site, you're likely to get even more buy-in, and even more cooperation, from those divisions further on down the line.

Now, if it is not obvious, one of the best ways to get this or any project underway is to have everyone who is even remotely connected with the project be at least familiar with the vocabulary of the Web; see that they have at least some basic skills to be able to go on-line. So you may need to do some training here for your team, and later on might consider holding training sessions for everyone in the organization.

These training sessions should also include some relevance for the department who requested to be included in these sessions. For example, how will the Web help your marketing people, your production or manufacturing people, your order fulfillment department? Think of ways that actual examples of functions that are performed by each department could be done more effectively by using the Web during these training sessions.

And I might suggest that you start this early on. There's enough hype around that people are interested; there's probably plenty of people in your organization that have some interest, but don't understand it, or don't know what's going on.

You will start getting company buy-in at all levels at this point in time. You also start getting your departments and divisions reasons to start buying in: "Oh, I didn't know we could do that."

But it also gives you a good opportunity to dispel a lot of myths. The typical example: in a publishing environment, on a project that I just completed here not too long ago, their production department, the people who put these manuscripts together in typeset form to go out to printers, were looking for an easier way to deliver this material to them, because they were spending \$450,000 on FedEx. Now, if there's any reason to build a site, that would probably be one of them. If they could cut that figure in half, that's over a quarter of a million dollars.

Now, when you consider technically the depth and breadth of the kind of files that they were talking about — where a four-color cover is about 80 meg, not counting the illustrative material that's inside and not even counting the text — try goosing that through switching packets on the Web and see if it arrives at the other end intact. Would you want to roll the dice on that as a publisher? I don't think so. So these are some of the myths that you might want to try to dispel at these early stages of this game.

You want to try and dismiss some of the over-inflated expectations that some people perceive are going to take place. "We're going to increase our business 10% by being there." Yeah? Not tomorrow, maybe. So you've got to get a little bit of sense of that urgency lowered, that "we need to be there tomorrow, we need to get this site up tomorrow." That isn't necessarily the right way to go.

The next thing you want to do, of course, is send the team off to surf, surf, and more surf for sites that reflect the features and flavor and texture that will suit your company's needs. There's also a copy of some of the acronyms and terms of Web vocabulary that are sitting up front here, along with data from that survey from *Yahoo*, for those of you that might want to pick up a copy and take it back with you.

Now, this is not some sort of plagiarism that I'm advocating here, and you might not see it in that light initially; but trust me, when your site is completed, it will in fact not be a rubber stamp of someone else's site, but be your very own unique site. Unless, of course, you decide to copy it verbatim, and you certainly don't want to do that.

Now, during this browsing or intelligence-gathering stage, it's extremely important that when interesting sites are located they be shared with everyone on the team.

One good way is to check out what's going on at *Yahoo*. They put up the "Top Ten Sites of the Week." You want to maybe assign that task to somebody, to look at least those ten sites and come back and report on it. But this sharing of information from the team — and I don't know how many people you may have at your disposal, or who will be involved in your team — but this sharing ought to go on at least once or twice an a week.

However, the number of interesting new sites that are going up on a daily basis may throw this phase into something that's unrealistic. Some of you might have several weeks at your disposal, and some of you may have longer; and if you let it, it could be a search for the Holy Grail, and take forever. So you want to put a timeline on this — or better yet, call it a deadline, because nothing has any importance in any business until it has a deadline.

And remember, the site you are building is going to be dynamic. It will change. In some companies, changes might take place quite frequently, and by that I mean maybe even monthly; with others, maybe once or twice a year at best. It really depends on the nature of your company's situation.

Now, during this stage you'll really have to be the glue that binds everyone together, to come to some sort of agreement on how your site will look and feel.

And by all means, keep it quiet until you're ready to present it to the powers-that-be. You don't want, at this stage, to have a lot of misinformation flying around the office for somebody to shoot down before you're really ready to fully explain and present your overall plan. I know this might be difficult, but the secret is no good unless you can tell somebody. So keep your team quiet, no matter how eager they are to share their excitement with others in the office.

Draw up some thumbnail sketches during the next phase, diagrams if necessary; and by all means don't try to create a finished product at this point.

First you want to bring all the divisions and departments back for a buy-in session of concepts that you believe will work for your company as a whole — not just address some of the divisions' needs, but the whole company. This phase may take some more selling, so your presentation should be as good as, if not better than, an ad agency pitching a new client; or I really should say, an ad agency pitching an old client on a new concept.

Keep in mind that we are selling concept here, and not necessarily a finished product. You do not, and I repeat, not, want to get into microscopic details at this stage.

Present your concept in generalities. Leave room for comments or suggestions. Some will be for the better; some maybe not so hot; but at least you've opened up some dialogue.

Even a bad comment or a suggestion may provoke some good ideas, so don't be so ready to turn off the bad ideas. Listen to them. They may give you directions on what you don't want to do. But more than likely, if you are a good listener and your team are good listeners, it will provoke some good ideas.

One thing that you want to keep in mind during these sessions is not to have any egos bruised at this point in time with criticism of those, quote, "bad suggestions."

Your goal is to build agreement and allies among the division leaders and others who may be involved, because you want to get approval from the top. As you heard from the last session, we put the CEO up there and everybody listened. It's also going to be a lot easier to sell downstream to other departments whose resources you may need to enlist to make this project more successful.

If there are disagreements, and there will be disagreements, let the division heads fight it out if necessary. You want to keep a conciliatory position; you want to keep it cool. It's okay to disagree, but do facilitate disagreeing agreeably.

What you're looking for at this point is a consensus of some sort of agreement, and you want to go away from this meeting with that in mind, even if it's only in principle.

Then what? Get the team together, now, at this point in time. Make sure that they're all on the same page, that the team are all wearing the same uniforms, and by all means know what the game plan is.

Now, if you've done your homework, you will probably have this ready to hand out the minute that meeting is over, with maybe some few minor changes.

At this point, by all means one thing you want to keep in mind, and this may be very difficult, is that you're going to need to have a lot of patience. Mistakes are going to happen. Expect them. Use it as a learning tool and as a growing experience, not only for the individual who made the mistake but for the whole team. You certainly don't want to pour salt in the wound. The person who makes a mistake, the last thing they want to do is to be reminded over and over again that it was a mistake. But if you can turn that around into an advantage, an advantage that really works well for everybody, then the person who made that mistake becomes a hero.

You don't want to dam up any enthusiasm at this point in time. You don't want people walking away bitching, saying, "Oh, that was my friend who just got criticized. I think I'm going to bow out of this project." You don't want any of that nonsense taking place; you don't need it. It's tough enough to get two people to agree on one single thing, let alone an entire team.

The important thing is that you want to keep everybody on the team in focus. Since we're talking about team, I think I'll use the "Vince Lombardi" theory of management. For those of you who don't know who Vince Lombardi was, he was a coach of the Green Bay Packers back in the late fifties and early sixties who won several championships for the Green Bay Packers, and went on to be a historical figure.

His theory was, "preparation, planning, and execution," and in that order. More often than not, we're all running off executing without preparing and planning. Keep the end in sight at all times. Keep the dynamics of the Web team focused with the end result very much in the big picture at all times.

Now you're ready to begin Phase I of your Web site. Keep in mind that you're not going to build a static site here, so other questions start rearing their ugly heads at this point. What happens after the site is up? First question: "Okay, we have a Home Page. Now what?"

The creature that you're constructing, or have just constructed, is going to need care and feeding, and lots of tender loving care. Who is going to be the "Webmaster?" What is going to be the nature of your content? Where is your content coming from? Who is going to contribute what, and when are they going to do it?

If you're depending on information that already resides in some database — for example, if you're putting catalogs up — the people that are in charge of this database need to be brought into this somewhere along the line. You're going to have to take that information and convert it to documents that are going to be able to be put up on the Web.

What about graphics, illustrative material? These are important issues that will need to be addressed. In talking about graphics, since I've raised that myself, don't make the mistake of drawing from two or three different sources for your graphics. Don't make the mistake of leaning too much on people who are print-oriented rather than video-oriented. If they have some savvy about the Web, use them by all means; if they do not, I would encourage you to make everything go outside. Look for a video company that does titles and credits which would probably be more appropriately placed on a video screen.

And here's where you want to consider putting a service-level agreement in place.

We've already mentioned the fact that you're going to have to depend on your database people. They're going to need to have some information that they can deal with in terms of timelines. If I've put a request in today, how long will it take me to get this back? Once I get it back, how much time is it going to take to mark it up? How much time is it going to take to include? How much testing do I need to do?

All of this needs to be documented somehow, in terms of a reasonable timeline that everyone can live with.

And also, in developing this kind of agreement — this kind of service-level agreement, if you will — it holds everybody in the chain responsible and accountable for their own, so you're also getting buy-in now, deeper and deeper and deeper. The more buy-in you get, the better off you are.

Particularly, I'm going to give you an example of what you might want to cover in this type of service-level agreement.

First of all, you want to call it something that everybody can identify with. From my example, I call it "shared venture — product information, on-line services systems and technology." These are the three divisions that I feel are going to be most involved. So we're calling it a shared venture.

Now, for product information, for example, what do we want from them? We want them to supply us catalog information. We want them to develop a program to pull that information, as needed, for the Web site. They will supply the graphics; by that I mean if there is illustrative material over and above. For example, if you are in the publishing industry and you want to show off the book cover, it would be incumbent upon them to pull that book cover together, have it scanned, whatever is necessary. So we're spelling out some real tasks here for that particular department.

They will test them on their side of the system. They will also set up a system to add automated links to supplementary materials such as transparencies, software, and other items that an object-oriented database might encompass.

So we've outlined these five elements that are going to have to come from that department.

Now, the on-line services department are the people who are going to be handling this project overall, and they're going to have some responsibilities also. They're going to need to test those links before they go anywhere, make sure all the GIFs come through, and add any corrections not related to the catalog, because the catalog may have gone out with 50 typos in it. You certainly don't want those typos to show up on your Web site. Fix them.

They'll set up a TAR file, if necessary, to send over to the systems people, who will then put it up on the Web.

But before that, they'll test it on both Mac and DOS platforms; I want to make sure this animal is going to work on both platforms. Even though there's a smaller percentage of Mac users, you don't want to overlook or offend this audience either.

They then should go over any corrections related to the printed catalog. Now, that should be incumbent upon that department, if they've caught these typos, to get it back and get it corrected before another catalog is printed.

They're going to keep a log of supplementary materials that need to be added; they're going to organize for these materials to be uploaded through an FTP site. And they're going to process Web mail; this is one really big issue, and I'm going to take a couple of extra minutes here.

When you get down to the level of e-mail, most people say, "Gee, isn't it wonderful? We get 60, 70 pieces of mail a day!" I've got a Webmaster here who doesn't know what to do with this Web mail that's coming in. Some of it may be relating to orders; some of it may be related to technical information about products and services; some of it may be even more in-depth than that.

So during this buy-in process, you're going to need for somebody to buy into this end of the game. You're going to need somebody from each of these various divisions who have the expertise and the level of experience to be able to answer some of this mail that your Webmaster probably cannot. This is also going to take some resources, so you better plan for it right in the very beginning.

Knowing e-mail — as I'm sure most of you do — when someone sends an e-mail, they expect a response in four to 24 hours. That's reasonable to expect. You may want to boilerplate some responses, if they are going to take a long period of time; by that I mean have a couple of prepared letters to go back out immediately, if you know this is going to take days or even weeks to get an answer. [For example,] "Thank you for your inquiry. We appreciate your interest. Please be advised that I am passing this information on to our technical department or our manufacturing department or whoever that happens to be; they will be back to you as directly as possible." This you can send off while you're there reading the mail. Button, the mail goes off.

You're also going to bring your systems people in, to be able to route this mail, so that you don't have to run it out in hard copy and walk around the building passing mail; so you're now looking at hardware issues as well. You look at your internal-connectivity issues as well. You're also looking at the buy-in process.

By now, everybody in the organization is now involved in the Web, at every level. So, even when you get down to that e-mail process, you certainly want to have been prepared for it before the stuff hits the fan and you say, "My God, I can't handle this," and you've got some poor person, male or female, pulling their hair out on a daily basis just trying to respond to 60 or 70 pieces of mail. And it is not unlikely that, if your company has any size and stature, this number could even grow larger.

And that's really what you want! This is the kind of interactivity that you want to get from the people who visit that site; because the better informed they can be, the quicker they start interacting with you, the sooner they will become a customer, or a better customer. And even if they don't, they'll go away talking about you, and that you cannot buy in advertising, PR, or anything else, when people are saying good things about you and your company.

Now, our staffing.... There are staffing problems, obviously. Some of this, you're going to have to make your own decisions on outsourcing. Students, as you heard from Jim a little earlier, are probably a good resource. They're excited; they're willing to work long hours, especially if you get a couple of good grad students who really need the money — and I've never in my life met a grad student that didn't need money — who are excited about the projects that they're working on, who will be able to contribute some real, good, solid advice sometimes, especially if you don't have any real good resident experts. Get somebody out of the best lab out of the best university that you can buy locally. Good source.

Now, what about mistakes? You're going to have all kinds of stuff happening up here. You're going to get those 404 messages. "What do you mean? It worked when we tested it." "All of a sudden it just disappeared."

One very important issue that you need to address again, right from the very beginning, and I'm going to close with this, is that of security. Who has access to the data that can be manipulated? What you don't want to happen is have people in your own company that are out there experimenting with their — "Well, this is my division, I'm allowed to do this." Beware, my friends; they are not! Be very selective as to who has total access to all of that data. What you don't want to happen is to turn your site on in the morning and find out that it's not there. Very, very frightening.

And I might make one other suggestion to you, in terms of when you're changing data on your Web site. You may want to download the entire site, add your data, test the whole damn thing all over again, and then upload the whole thing. In other words, flush the old system down the proverbial —, and start brand new. What you don't want to happen is mistakes going back up over and over and over again. If you flushed it, you know it's gone; however, you may find some new ones.

Thank you, ladies and gentlemen. I appreciate your time. I hope I've humbly been able to share some poignant experiences with you, and I hope this information is of help to you.

If you have enjoyed any part of this, my name is Ken Lang. If you haven't, it's Alan Meckler.

WORLDWIDE WEB LOW-BANDWIDTH DESIGN: HIGH-TECH, LOW CLASS

MODERATOR

Ken Lane

WWW and On-line Information Consultant

SPEAKER

Jaime Levy

Creative Director, *Word Magazine*, Icon

Ken Lane: Welcome to the final portion of this afternoon's conference session. Before I introduce our next presenter, for those of you who don't have good light and don't write fast, there will be copies of an audio tape of this and all the other sessions as well as a CD-ROM for the entire conference available. These will be for sale at the booths near registration. So if you want to get a copy of this or any other tape, [it will be available]. And I have been promised the airplanes will be eliminated from the tape, so there will be some blips. Like President Nixon's seventeen minutes, they will disappear. And I understand the editors do that quite well.

The format for this session will be that the presenter will speak for about 45 minutes, and we will allow for about 15 minutes of Q&A, so hold your questions until the end. You might want to take some notes and remind yourself what you might want to ask.

It gives me a great deal of pleasure to present our next speaker. Her name is Jaime Levy, and she is the creative director of *Word Magazine*, a commercial electronic publication distributed via the Web. Her responsibilities are to design *Word* using HTML and to push the envelope of the Web with regard to integrating multimedia interface design and user feedback. She also does Web design for Icon clients, many of whom are from New York City's publishing and music industry. Prior to her role at IconNet Jaime published a disk-based electronic magazine called *Electronic Hollywood*, as well as the interactive disk-based press kit that went out with Billy Idol's album *Cyberpunk*. She teaches a class in electronic publishing at NYU's interactive telecommunications program and was recently recognized by *Newsweek* in their February 27th edition as one of the top fifty people to watch in interactive media. Ladies and gentleman, Jaime Levy.

Jaime Levy: Thanks for coming out to this tent and thanks to Meckler for having me here. It's really nice. What this presentation is supposed to be about is low-bandwidth design, but I'm going to expand it to something more futuristic and exciting — to multimedia integrative design. That way I can sneak in some more of my later work, which I don't necessarily call low-bandwidth anymore.

I should probably start off with defining what low-bandwidth design is. What it meant to me five years ago when I started electronic publishing was trying to jam as much information as I can onto a floppy disk. This was before there were these CD-ROM things. I wanted to make an electronic magazine, and I was going graduate school at NYU. I decided for my master thesis I was going to do an electronic magazine on floppy disk in this *Hypercard* language. It was called [inaudible].

It was really kind of tough to figure out how to make the graphics so they would be small and make the sounds so they would be small, and then make the text and everything integrated together so I could put it on a disk and mail it out to people and sell them. So that was how I got my start. And the whole point of it back then was to be able to distribute my animations, because everyone has a floppy disk in their computer. They even do now, so my

disks aren't out of date yet. But one day they probably will be, as soon as we stop having these floppy disk drives.

That was a big issue. I wanted to make something and distribute it myself. I didn't want to — my background was in film and I originally wanted to direct movies. I could make my video art or my movies, but to get them out to where people could see them is a really big deal, as we know. But it wasn't such a big deal to distribute my disks — though at first, actually it was. I'll tell you what happened, but before I get into that I'm going to back into this low-bandwidth design thing.

I was doing these disk magazines. So you have this information and it's small and you want to get it out to people. We have two things now; we have these *Director* disk-based animations that I've made the last few years, and now we have this Internet thing. And what do they have in common? Well, what they have common is the Internet is still — pretty much most users are coming to it from a 14.4 or 28.8 modem, and they are still clicking and waiting, which really sucks. Remember the old CD-ROM, the single-speed drives, how you'd click and it would load up another animation? They were pretty bad. Most CD-ROMs are still pretty bad to me, but the point is that with the Internet I don't think it's too exciting for people to click and wait. I'm still seeing a lot of cross-over now with doing these disk-based animations because you can now distribute them over the Internet.

Okay, you're saying, how? I don't know if you're familiar with *Director*, but it's one of our great authoring languages for making animation. It's going to premier in a few months with a *Netscape* where you can click and download a *Director* animation. So I'm going to be happening again, because I'll be able to use my disk space animations from before and distribute them over the Internet because they're small. That's really good news because most people don't know how to do that. I can prove it to you because there aren't that many other disk-based electronic presentations out there.

When I did the first IPK — they didn't even call it IPK back then — it was Billy Idol's. They wanted to do this direct. He went into a bookstore and bought one of my electronic magazines on disk and went, "Oh, I want to have one of these with my new album *Cyberpunk*," because he got into this "cyberpunk" thing. So his people called my people and said, "Would you do a disk-based animation for us? We're going to try and distribute it out with the record." And this was very exciting because no one had ever done this before.

And here I was, making my little disk-based animations, driving them to bookstores and selling them for \$5. And now, all of a sudden, someone was going to package them with a CD and put them into record stores. And people were going to pay \$20, or whatever they were selling them for. They sold 18,000 of them, which was a really big deal. So it was fine and something I made became commercial and they were selling it, so it was like "hooray for low-bandwidth design."

But then what happened was that no one followed up on it. There are a few other bands that did IPKs, but they didn't become common. What did become common is musical promotion over the Internet, so it's kind of interesting because there's been a lot of change and I never knew what was going to happen.

Way back when, in the early '90s, four or five years ago, a friend of mine who was on the original Apple team — I was exhibiting my electronic magazines at a trade show and they felt sorry for me because I was a girl and I was an artist and I was making these animations. They said, "We'll let you have a booth, you can set up your Mac II and you can exhibit your electronic magazines."

Anyway this guy from Apple came by and said, "Wow, this is great, you're thinking ahead. You're thinking about low-bandwidth design." He used those words: "You're thinking about trying to get as much information into as small amount of space as possible. That's going

to be really important. There's going to be this thing, this big network coming down, and one day people are going to buy your electronic magazine, cha-chink, cha-chink, and they're going to put their credit card and the money's going to go right into my savings account and it's going to be great." I totally didn't believe that. I hated the modem and the Internet or whatever it was back then. The idea of sending text wasn't very exciting. I didn't imagine the WorldWide Web back then. But now it's here and *Director* is happening with it, and it's getting really, really exciting. So anyway I think I've talked enough — I'm ready to show stuff now. So I'm going to show some stuff.

I guess I'll start with *Word*, because here it is. *Word* is this electronic magazine that we started, and it came out on the Web on June 26th. It's an interesting experience at Icon because it was just — when they decided to do electronic publications and Web design, it was just me. And then we hired two more people and we have a lot of clients now. It's huge, the amount of stuff we're producing, but the office hasn't gotten any bigger. It's just the three of us.

And where are all these designers? Well, the cool thing about it is they're not in our office. They are away from us. They are out in Internet-land, and I don't have to see them or talk to them on the phone, but they're still designing for *Word*. So a lot of stuff you're going to see I have overseen as an Art Director, as Creative Director, but I was able to art direct over the Internet. So what's very interesting is this was — we're not only seeing a product that's distributed over the Internet, the way it was created, the communication, was done over the Internet.

I'm going to show a few pieces, and if they happen to be low-bandwidth design, I'll point them out especially. Here's one that just went up. I should tell you something about the *Word* interface or what it is; *Word* is a short story literary magazine. It's interesting to me because, well, first of all, I was publishing electronic magazines and short stories before, so this is where I wanted to go. It wouldn't be so exciting to dress up a story about the latest Pentium chip. There would be no reason to make it look very cool or to have much exciting navigation or perhaps a BBS behind it. But with short stories you can do that, because they are creative to begin with. That's another cool thing about *Word*.

So we have a combination of short stories and these integrative multimedia apps that we're putting together. The staff just isn't that big but, as I said, there are a lot people working on it. But they are all over the country, or all over the world actually.

I'll tell you a couple of secrets. *Word* is different. That's one thing you can't have with CD-ROMs. You put the CD-ROM into your computer and you play it, and then you shut it off and then go pick up your kids at school, and then you come back and you play it again. Guess what? It's probably going to be the same exact first screen. Maybe it will have a non-linear subtext or something, but with most CD-ROMs — you have your gaming experience, but they are built as they are, and they call them interactive and they called them dynamic but it's not connected anywhere else. It is what it is, and that's what it is. It doesn't thrill me that much, to tell you the truth. But *Word* is so thrilling because it changes a lot.

You see that banner? I don't know if you can read it, but it says, "Issues Culture Plenum." Every ten minutes that banner changes and the color of that banner changes, which is really nice. So every time you come to work the banner is different. There's something different about the page. What else is different? The icon bar going down the side: "Table of Contents — Money, Travel, Machine."

Now, we have sponsors in *Word*. That's how they pay our salaries supposedly, so we have to give them certain amounts of stuff so they give us money. So part of the way that works is we give them flashscreen ads that you'll see, and they get their little banners at the top. But there are some complaints, because the guy who sponsored "Money," let's say, was getting more hits than the guy who sponsored, let's say, "Gigi" at the very bottom, because

people generally click what's at the top of the screen when they're cruising around. So what we had to do was come up with this rotating icon bar, and every ten minutes the icon bar — so "Travel" will go up one and "Money" will go down to the bottom. It will keep going like this. Pretty neat, huh?

What else changes about this first screen? The stories. By law we are supposed to put up new content every week in *Word*, so we are trying to put up an average of three stories a week, which is okay, but it will probably be more soon. But that's the minimum. That's just stories. We're always building other stuff into it. But that means the front screen, every time you come there, whatever is new, you see it right away so you don't have to go plodding through looking for whatever is a new thing.

Let's check something out. Here, I'll show you, I'll prove to you that it's true. I'm going to reload the screen, okay? Now remember, "Money" is at the top and then the purple banner — that's going to go to *Word*, you say?

Okay, so let's talk, talking painting. There's your ad, a "Meta-ad" for Netscape — a great product, right? This piece I'm particularly proud of because I really feel that I used the medium. I don't always do that, but this time I did. It's a painting that talks, hence the title.

I like this guy named Jonas Hall. He's from [inaudible] and all their band and he does spoken word. He's on MTV a lot and he's very funny. Then my friend, Michael, he's a Soho artist. They would normally never work together or know each other at all. Jonas Hall spoke thirty poems for us and he gave them to me on real audio — not real audio for me. He gave them to me on a cassette and then I made them into real audio samples. Real audio is a great data-streaming technology that we're using right now to play audio in real-time on *Word*. You'll hear it, hopefully.

Anyway, so what I basically did was make it combine a painter and a spoken-word person and a programmer, our genius programmer at Icon to help us make this app, where when they click on the banner up here it repaints the painting. Isn't that great? Good.

Hold on, maybe, there he goes. We should get three new images. And you click on the art and hear the spoken word that goes with that image. Here, let's try to find one that's cool. I'll click on that one, an audio piece.

Presentation

M: What am I saying and why and what are my motives? Number two, if I knew it all along why didn't I stop before I started? Number three, why have I not gone to a [inaudible] since 1989? Number four, hey, what was that? Number four. Number five, if I'm so sure that the worst of it's over, why is my apartment booby-trapped, why do I have six mailing addresses, how come I never answer the phone?

Jaime Levy: So basically it's a different way to access poetry or to even experience it. The cool thing about real audio is that you don't even have to be on the page to hear it, you can even put it out on *Netscape* and it will keep streaming. So if you're really into these spoken word...

Anyway, I'll play one more just a bit. I think you've got the basic idea of this application. They're really funny, you should come check it out.

Presentation

M: It would shrink, of course...

Jaime Levy: So let that go. I'm going to click back. Now I'm copying it to the machine section, and I'm going to show a couple of different pieces where I integrate multimedia. "Cybergothic" is a basic photo essay. This I would consider a little bandwidth. Each image is 40K. They're

grayscale JPEGs, but you don't have to — if it's not downloading thirteen images when you come to this it downloads just the bottom bit, the "Cybergothic" by Scott, and the two icons below it and then with the CGI it's throwing or pushing these images to us. So basically you're not wondering if this is done yet, because it's not a matter of downloading. It's almost like the real audio in the sense that it's coming at you and you can quit out whenever you want. It's not like you haven't completely built that page. So that's what that's like. Let's see; I could turn off this now.

Okay, I'm going to hop over to another place and show you a couple other pieces. How about just a regular story? We'll sort of scan through it. Generally, for stories in *Word*, I ask the designers to break the story so there's never more than a paragraph per page, but because this story was designed with HTML I can make an exception, and also because she designed it vertically.

These are two things to be concerned with in low-bandwidth design. One is that if you design something horizontally, the way that *Netscape* loads images and everything on the page, it will end like this. So if you've got something that's super-wide, it's going to take a long time to load. But if we have it like this, by the time that they're ready to scroll down it will be there.

When I talk about HTML text I'm talking about this stuff right here. This stuff doesn't take up any time to download. You want to use this stuff. You also have to make it look good. It's hard to make HTML look good. It actually takes a little bit of tweaking. I should just do it now.

The Web sucks. The Web is so ugly. It's not even that *Word* is so great, it's just that everything else out there is so bad. It's like public access. I just can't believe it. I mean, I'm so happy that everyone's empowered and people can design their own Pages and put them up on the Web, but it just looks [terrible]. I mean, I don't even want to look at it. You know, you go to this stuff and you look at it and it's just, you know, they don't take any care.

Remember desktop publishing? That's how I supported myself when I did graduate school. I didn't know anything about design. I would go in and root for an account; they were looking for a designer, and if I can turn on the Mac they'd hire me. I had to learn design by faking my way though. People are doing that. They call themselves "HTML designers," but they're not designers. They say they know HTML — big deal. You can learn HTML in a day. Design takes a long time.

All right. Now this piece of text here, as you can tell, is a bitmap. So we have bitmap text and HTML text. Now, bitmap text, of course, has to be downloaded, so let's try to make our bitmaps as low-bandwidth as possible — which means as few pixels as possible, which mean it's as few colors as possible.

So how do we make things in fewer colors? There's a couple of ways. You can start with your RGB image in *PhotoShop* and then you go to index color for your GIFs. You have your choice of 8-bit, 7-bit, 6-bit, 5-bit. What I like to do is, in *PhotoShop* — we're getting technical here. I'll tell you my image and I'll go "Command-A," which selects it, and then I'll go "Command-C," which copies it. Then I'll go "Command-N and Command-V," and I'll just paste it. And I'll make that same image, I'll make five of them up on the screen.

And then I'll go up and index it at 8-bit and then 7-bit, and then 6-bit and then 5-bit, and go all the way. And then look at them and say, "What can I get away with here — the lowest number of colors?" That's really key. People keep putting up these images that are 8-bit, saved as 8-bit, and they only have sixteen colors. They should be saved as 4-bit. These are things to concern yourself with.

If you don't understand these things then do it the safe way, which is the way that I just explained, which is slowly going down from 8-bit to 7-bit, and see how low you can go before it starts looking really bad. That's one thing to think about.

Another thing that you can do — I'll just keep cruising though. The way this piece is, this is the hypertext thing, so if we click on the flame you get a picture. Ah, that's nice. This is what I like, you've got your screen, you've got your little piece of text, you can see it all. It's easy to navigate.

One thing, this rule in *Word* is a little absurd — I don't really believe people do it — we make it so they never have to click outside of the *Word* world. They never have to come up and click back, God forbid. That's real important to us. But what that is, that is navigation. That's another thing I concern myself with a lot. So basically I can go "Next," and see how it's loading from top down, so I can read, read, read, but actually if we jam down here, it might still be loaded pretty fast, because we're in ISDN — yippee!

Okay. Let's keep cruising though. I'll show you another piece. Let's see, how about this. This is "[Ambyer] Realm." I'll give you an example. It's about ambient music. I'm a big fan of that kind of music, so I asked three DJs to give me a 45-minute tape and I made them into real audio, so you can listen to 45 minutes of music and do what you do. That's really, really exciting to me. And you can also find out about the guy who made it by clicking on the guy. You click on the turntable, you hear the music. You click on the guy to hear what it is. Is it playing? You can't hear the sound? It's so ambient you can't even hear it.

I like to leave instructions: you click there and it tells you all the things you need to know. Very exciting. Oh, there we go, so we can hear. And real audio is real exciting to work with, just because I'm so used to *Director*. When I did my disk-based stuff, I had to have these annoying five-second loops. Anyway, we'll get to that in a second.

I've got to tell you something very funny. Roxanna's nails — Roxanna is the secretary at Icon. We have this deal that in exchange for her content we'll have her nails done. So this is an example of that. So you can see her nails and hear her talk about them.

Presentation

W: Hello again and welcome. You are on the WorldWide Web with me, Roxanna of the CNN, The CyberNails Network. All right. You know what it's like, it's like nails, when you were a little kid you went to the store you bought some fingernail polish and you paint your nails that way. Like my typewriter, but today there's technology involved.

Jaime Levy: All right. You've got the basic idea of that. I'll just show you a couple quick things in *Word*. I want to show the electronic magazines. I should probably show you some of the backbone behind *Word*, which is the BBS; that's sort of interesting. After you read the story you can interact, if you register in *Word* with the with the other people. You can basically pick a topic — we have one here — and how many you want to see viewed of those responses and join the discussion and see what they're saying about that story. This is about somebody's trip to Morocco and you can say, "I like it" and submit the message and you post it. It's so easy.

Anyway, there's these BBSs behind most of the stories in *Word*. We're trying to move in that direction and have chats integrated so people can — they aren't just there to read our stuff and be entertained, but also to interact with each other. That's part of the Web or using the medium.

I'll show you one more story. I'm going to show you an example of a story that is not low-bandwidth designed. I can pick on it because I did it, and it was a big mistake. It was what I did at the very beginning because I wanted to do something slick. We don't allow this anymore. Right now when I have designers design stories for *Word*, I give them a 60K image limitation per page. They can have 20 images but they better not add up to more than 60K. This one does because I went for this bitmap text idea over these heavy backgrounds. These images

right here are a little bit too big, and so this story can be a bit slow loading on a 14.4 or 28.8 modem, which is why you should avoid using bitmap text if you can. On this page you'll notice I used the same image in the background as I did on the previous page. That is good because it goes into cache, which is important because it doesn't have to load again. We try to use that a lot in *Word*.

I've got to show you a page I really like. I took this picture in San Francisco of this piece of [stuff] on the ground, and I put it in the background. Isn't that cool? Well it's like this part here, it's about [stuff].

I feel so strange telling these tricks because they're so — I'm so dated I could be crossed out in a year or two. I think and I hope this whole low-bandwidth issue is really going to go away. I really believe that. I'm one of those people that believes that the Internet is going to be on TV really soon, or something like TV, where people are going to be sitting on their couches with the popcorn and their little keyboard and they're going to be browsing. We'll stop calling *Word* a magazine — we'll call it programming. It's going to be like watching TV, but you'll be browsing the Web. It will be fast and we won't have to worry about these things, because most people don't want to worry about it.

A friend of mine who works at Prodigy has designed their big music site. She said to me "Oh God, I'm working with this designer, he's really awful. He's never done the Web stuff, so he keeps designing like a whole page of a magazine. He gives me this big, big GIF image because he doesn't understand how to do low-bandwidth design and break it into little pieces and deal with loading problems. And he doesn't want to deal with it. I'm going to have to get rid of him." And I said, "That's really sad, because he's a really good designer, but he's not open to trying these new things." There's not really a place that you can read about this stuff. It's a lot of experimenting.

One program that I highly recommend to everybody designing Web sites is the *DeBabelizer*. It is a magical program. You can use this program even if you are a total nitwit. All you have to do is open it up and then you go, "Command-O," like with anything else in the world on the Mac, and then you open up your GIF image and all you do is go, "Save." Check this out. One-half to one-third the size of the original — pretty cool. Do that to every image on your Web site except for transparent ones, and it will make them load faster. It's so easy. That's my spiel about the *DeBabelizer*. I want to recommend it.

I'm going to hop out of *Word* for a second and show some — back in the early days when I was doing my electronic magazine stuff, and why this *Director* stuff is coming back into being important again, as I said, is because of *Shock Wave*. And *Shock Wave* is this new technology — *Director* and *Netscape* working together so you can download *Director* movies. How it's going to work is, basically, you know how when you've gone to a page in *Netscape*, if it's 50K it pretty much just downloads and you're there. If you can make a 50K movie then it will download and play instantly. So it's becoming important again to figure out how to do these movies that aren't very large. You can do so much more animation in *Director* than even in the much-hyped *Java*.

I'll prove it to you. I'm going to show you this disk. You bought this at Tower a few years ago if you liked Billy Idol. And here it was, and anyway I'm going to play that disk and why I'm showing the disk is because it's not a CD-ROM. I told you, I hate CD-ROMs because they are so stupid, you make this digital thing and then you put them on this thing and then it's like you put it back on paper again. It's like digital to paper — it just doesn't make any sense to me. If you're going to make something digital, just stay digital, and it's going to package and paper and be sold in book stores. I can't wait until they go away, but anyway, they're fine. It seems to me that with CD-ROMs people are confusing a storage format with a distribution format. But anyway, let's not get into that.

So, this disk here, again it's on the disk — I keep showing the disk because it's like a magic trick. It runs off the floppy disk, which means it's small. That is important, because that means that it can be copied. It's about fifty cents to make these disks. Anyway I'll show, though you got the idea, I'm sure. So, I'm going to click on it — oh boy, here we go. I'm going to point out the low-bandwidth things behind this. Can you hear me? All right.

This is the main interface of this Billy Idol disk. It loaded pretty fast, and that is because I'm using things in *Director* that don't take up any space in terms of art space or kilobytes on the floppy disk. They don't have to be loaded. They're just like calculations or something within *Director*; they're re-drawn and they don't take any time. That's how I understand it. I don't have a programming background, but I know what they are and this is what they are.

Color-cycling is instantaneous and doesn't take up any room. Great effect. Ink effects, all of that, in *Director*. Stretching images. It doesn't take any space to stretch an image. This Billy picture right here is only so big, but I stretched it. Yes, it "pixelates," but when you make it all messed up with the color-cycling, who cares?

Okay. The concepts, long lyrics, digi-art, they're basically on just black little back grounds. Within *Director* you can make this red or white with *QuickDraw* ink effects. I do a lot of animation with that. This thing across the top, that doesn't take any space, it's just this Billy Idol font going smush, smush, smush. I don't have thirty different fonts up there. It's just one piece of artwork, so I'll just cruise through this. If you start breaking it into pieces you realize, with all of these, that the reason it loads fast is because I'm not using that much art. I'm being very resourceful, or trying to be. Like here he is; his eye is the same piece of artwork four times, with different ink effects. We've got the top two, then the bottom two. So you can do these presentations.

This text here I actually loaded with the *Font DA Mover* into the *Director* app. They tell you not to do that, but I don't listen to them anyway. That way you can have the cool font. You can have as much text as you want within *Director*, — it doesn't take up any space, except like 10K. You can color it, you can bold it, you can whatever; you can't adjust your leading, though.

Anyway, you can do stuff like this. All this text did not take any space, so you can imagine that if we even took this part of this presentation out and saved it and made it downloadable from the Web, we can make some interesting-looking stuff. People like to look at things that move around on the screen. It keeps them excited.

I've got this crazy animation and animated text. Listen to the soundtrack. Could you put it up for a second? It's really crazy. I'll explain what it is after you hear it.

Presentation
M: [inaudible]

Jaime Levy: I have five to ten three-second samples, but I just butt them up against each other in *Director* across the score to create more sounds. You can have two tracks in *Director*, so you put one on the top and one on the bottom and all of a sudden you have a different sound. By butting them side by side or below each other, instead of just having ten samples you have many, many more. And that's a good thing to do in these *Director* presentations.

By the way, when these download into *Netscape*, which you will be seeing a lot of in a few months, they will have sync sound, which you cannot have with real audio on the Web. They will have interactivity. All this clicking, everything that you see here, will be working off on the Web, and hopefully it will be inside the browser soon enough. It's just a more dynamic, more exciting presentation. You know, things blink — you can't have things blinking, except for maybe one word of text, like this. That's the basic idea, you click on this and it's so great.

I'll show examples of two animations that I created that are low-bandwidth animations. This whole — to go through everything on here — literally to read everything, it takes about 15 minutes, and this can be stuffed down to about 500K. So there's some usefulness to this, at least right now, in 1995.

This is just using the tiling effects in *Director*. You just make the image into a tile and it — it's really crazy. This one is just using the same images and a paint brush and just swirling it around. It's not beautiful or amazing or anything, but it's low-bandwidth. I think you're getting the basic idea now.

Let's show another thing I did, which was this. You can't buy these any more except at St. Marks Books in New York, but I had five book distributors for them. I had a thousand made and there's only two hundred left; I'm keeping them for the future. Anyway, inside is a floppy disk and it's a whole book. It takes two hours to read and it's on a disk. But it's compressed on a disk, as opposed to playing off the disk. I'm still excited that I was able to do that, because it was total hell. I'm going to show what that is.

What I did was I got the rights from Jaime Hernandez, who has done *Love It or Rock It* comic books for five years. I was able to re-scan everything and put it into a news story. It's a 100-page manuscript about this drug dealer who escapes from rehab and they get chopped up. I got Mike Watt to do the music. I got a horror story writer and Jaime Hernandez and a woman from *Voyager* to help me edit it. We put together this electronic book on disk.

What preceded this were just the expanded books from *Voyager* that were not real exciting — they were just text on a disk. What you have here is animation, music, a little interactivity. My rules are I try to keep things very simple, using basic interfaces. This is black and white because, guess what, 1-bit artwork doesn't take up hardly any space. I have a bookmark programmed in here so if you only make it halfway through and you want to quit out, it saves the space, so the next time you come back it takes you right there by clicking on the bookmark. How ingenious.

Okay. I'm just going to cruise through — you get the basic idea. All this text here is just ASCII text. I loaded the font into *Director*, so that way you can look at it and it looks great, but it's not like they can steal the font. They don't have the printer font, they just have the screen font and they only have it at two sizes; that way you can have this much text and it takes up no space. That's how I did this novel: using ASCII text, but loading it in.

I didn't want my interface cluttered up, so basically you see one piece of artwork and a paragraph of text per screen, with animation. Basically, it's an electronic book. It was a lot of fun. It took a year of my life and it sells for \$15. The real exciting thing to me is, as I said before, that I was able to stuff all this information on a floppy disk.

I think I pretty much went over what I wanted to say. So I guess we could open it up to questions. I'll demo some more stuff if you want. Should I do that?

M: Tell us some more about [inaudible].

Jaime Levy: The platform I design for?

M: What's the minimum [inaudible]?

Jaime Levy: I design for 256 colors, 8-bit for the Mac and for the PC. We check everything that we do. We do it on the Mac and then we check it on the PC to make sure it looks good. There's a lot of issues with that.

When you're designing for the Mac you have a lot more screen real estate than you do for the PC, so we have to cut that down. I give the designers a 500-pixel width maximum for

pictures in terms of interface imagery so it doesn't fall off the screen, you just have to scroll to the side. There's not too many different things, except that the dithering on the PC — a lot of people have 16 colors and the backgrounds can look really bad, so you have to have everything looked at under 16 colors. They'll tell you they can't read that text over that background. That happens a lot to us.

W: [inaudible]

Jaime Levy: I'm sorry, say that again.

W: [inaudible]

Jaime Levy: To load the font into *Director*? How to do that? This *Font DA Mover* program — they don't tell you this, but with *Font DA Mover* you go "Open" on the left side, and it opens up all the fonts in your system folder. On the right side you hit the option key down on the keyboard and then you hit "Open." And you can open up your *Director* movies so you can stuff resources in there. What you do is you stuff text, you stuff the font. That way you can have ton of text in *Director* and have it take up virtually no room.

M: What are your, what do you mean setting [inaudible]?

Jaime Levy: For designing on the Web?

M: Yeah.

Jaime Levy: Everyday when I turn on my computer the most important program that comes up is *Eudora*, believe it or not. It's a great e-mail program because it's so easy to send and receive detached files. I'm art directing a lot over the Internet, where people send me their work and I look at it and say, "That looks [terrible]. Do this," and e-mail it back. There's *Eudora*, there's *PhotoShop*, of course with *KPT* — *Kai's Power Tools* are good for doing some things. *BB Edit* is an HTML editing program I use. I could use any of them, but I like *BB Edit* because it was the first one I used. What else? *BB Edit* and *DeBabelizer*, as I mentioned before.

M: [inaudible]

Jaime Levy: What?

M: How do you spell that?

Jaime Levy: *DeBabelizer*? D-E-B-A-B-E-L-I-Z-E-R. It's a great program. You can do batch files in it. It's really cool. You've got your artwork, you've got all your PICT files — like here, check this out. I'll tell you a secret. Check this out. Where's my place? Well, let's go here. You can do fake animation over the Web. I did that here.

This is not a low-bandwidth presentation, this is a high-bandwidth presentation. I'll show you something funny — no I won't — oh, stop it. (Come on. All right, there it is.)

How I used a "bab" in this program: this is a 360 degree walk-through of space with animated video projecting, so you click — here, we'll put the soundtrack on. It's annoying. It's me and my friends sitting in a cafe talking about stuff, slacker stuff. So you go in the door and you're in this room and you can rotate around this place's four walls. On each of the four walls

is projected video, which were just digitized video basically; this is *QuickTime*. There they are, smack in the middle. There is coffee imagery. You can click on the bloody O.J. glove and the wall rotates to the right, so you have whole new projection.

How did I do this cool animated video? *DeBabelizer* played a big part in it. What I did was I grabbed the video and then — in *Premier* you say “animate,” you edit the video so you have the part you want and you animated the PICTs. Let’s say you want ten seconds, but only two frames per second, so you figure that part out. It animates the PICTs, so then you have these PICT files...

[Tape change]

W: [inaudible]

Jaime Levy: Do I use CGI scripts to rotate the images?

W: [inaudible]

Jaime Levy: You mean on the first page? Yeah, those are CGI scripts for the icon bar and for the banner at the top.

W: [inaudible]

Jaime Levy: I’m sorry, I can’t hear you.

W: [inaudible]

Jaime Levy: Who wrote the scripts?

W: Yeah.

Jaime Levy: Our programmers. And they are for sale.

M: [inaudible]

Jaime Levy: A CGI script?

M: [inaudible]

Jaime Levy: Yes, and the thing about these scripts is that you have the programmers write them so you can reuse them over and over again. Basically, as I said, can you write me this script and I just dump 100 pictures — I’ll use the same names — but if I dump another 100 pictures in there, it will just take those and use them, even if I only put in 64 one week and 83 another week. And they can write scripts like that so you can have pieces like this where you can keep using them over. The animations in *Word* change a lot for just using the same scripts. And they are just basic C code. So it’s really useful to get a higher C programmer to work with that speaks English, because you can do a lot more.

M: [inaudible]

Jaime Levy: I'm sorry?

M: [inaudible] DPI?

Jaime Levy: What's DPI?

M: [inaudible]

Jaime Levy: DPI? Dots per inch? Always 72. Always. In *PhotoShop* when you get these high resolution pictures, the first thing you do when you get them from — you're working with these agencies that always give us these Quark files and they want to take this brochure and make it into a Web site, and they've got these like 300-DPI images; you make them 72 immediately.

W: [inaudible]

Jaime Levy: You can't use it for what?

W: [inaudible]

Jaime Levy: Yeah, if you re-save a transparent image in *DeBabelizer* it won't be transparent anymore, but it will be smaller.

W: [inaudible]

Jaime Levy: Yeah, yeah. You can then open it up in transparent and it will make it bigger and transparent. It's really cool. I love that. Don't you just love the Web? It's so wonderful. Is that it? Oh, yeah, go ahead.

M: [inaudible]

Jaime Levy: The what?

M: [inaudible]

Jaime Levy: *Director*?

M: [inaudible]

Jaime Levy: Oh, you mean the program?

M: *Word*.

Jaime Levy: *Word*? What do you mean? You're looking at *Word*. It's right here. I mean, you know, it is what it is. You don't even need me to show it to you, because it's for free. You can just go to www.word.com, when you are in the cafe with the Web access or at your home, and you can see it for yourself. It's so wonderful.

Oh, we're getting nice broken images here. Don't ask me why. I mean I could just cruise through here, but I'm going to stay away from this story because it's being naughty. Are there

any other questions? Did you see that, how it delays? That's a good one. Here's a new story, this one's actually fairly fast-loading. Oh, getting lots of chops. Help.

Are there any other questions?

M: [inaudible]

Jaime Levy: When I say design vertically — what if I show you an example of something that's designed horizontally, that takes forever to load, and then you'll get it. We'll work backwards. When stories have been in *Word* for two months and they're old and they die, what we do is we put them in "Dead Word," which is in the *Word* Info Section. There it is, *Dead Word*. And that's where I put my horizontally-designed stories. Here's a good one. As we see, there it goes, so check this out. It's so slow. Awful. Isn't that awful? It's because it's horizontal and it's trying to draw.

But what's nice about this story, though, is that I hired a video artist for \$100 to just go shoot pictures of people smoking. We just grabbed them and they came out looking really nice. Bad design idea, but the pictures came out looking pretty good.

Any questions? I can't see anything.

M: [inaudible]

Jaime Levy: Re-map text?

M: [inaudible]

Jaime Levy: This is bitmap text. That's why it looks like — that's why it's so slow, because it's bitmap and it's horizontal. We've done horizontal design with HTML text; it's a little bit faster, but it's still that same issue the way it loads, so we are looking at only just this part of the screen, but it still has to load everything to the right of it. So you have to be careful of that.

I guess that's it.

INTERNET TECHNICAL WARPING THE INTERNET WITH OS/2 WARP

SPEAKER

David Moskowitz

Co-author, *OS/2 Warp Unleashed*, Productivity Solutions, Inc.

David Moskowitz: [Hello, I'm David] Moskowitz. I have a hand in a small book that we're going to give away at the end of this session, called *OS/2 Warp Unleashed*. Also, depending on how many other people come in, we may end up dealing with another copy of this as well. But in order to do that, everybody should have two forms, one a yellow and the other a white form. That white form is an evaluation form, and we're going to draw the winner from that white form. That does not replace the speaker evaluation that Mecklermedia may also ask you to do as well. This is for us.

M: [inaudible]

David Moskowitz: You don't have any of those forms. Is there anybody else who doesn't have one of the forms? I think we can fix you up. One of each, a yellow and a white. We used to do this with both sheets the same color. Those of you that are speakers, who ever do this type of stuff, if you make each page a different color then you don't have to tell people that they're supposed to have three pages. There's something about growing up in the post-Sesame Street generation — we've forgotten how to count sometimes. So if you say you should have a white one and a yellow one and a green one and blue one, as long as people aren't blue-green color blind, you don't have too much of a problem. Of course if somebody is color blind, then this doesn't look the way it should either.

Part of what we're going to be doing today, in the hour that we have, is look at why OS/2 makes sense to deal with Internet communications. We'll look specifically at OS/2 and the Internet and then we'll get into some of the technical stuff about what it takes to make OS/2 work. Finally, we'll do a brief demo. These systems are not connected to the Internet so the demos will be local, and we'll show you what's available.

But the real reason that I'm here, more than going through the particular presentation material, is to try and answer your questions. So to that end, if you have a question, please ask it. I can't begin to guess at what you don't know. Because of the difference in lighting and whatever, if I'm in the well of lights that's there, it may be difficult to see you, so please don't hesitate to say something or make yourself more obvious than just a handshake. That's rule number one — if you have a question, I'll answer it, even if it's, "I don't know."

Rule number two, however is that if I ask questions, dead silence doesn't cut it. Okay? Hello, that was a test. That will work, as long as it's not dead silence. Anybody here that English is not your native language? One person — you have an excuse. Everybody else, no.

Did anybody, when you were growing up, have a teacher that was out of the days with the one- room school house? I did, a Miss Crumb, appropriately named when you stop and think about it. For seventh grade she taught us that when the voice goes up, it means it's a question. I'm working hard, I know.

Can we try this again, is everybody here, alive and well on Monday morning? Okay that's better. I understand it's rough.

The question is, why use OS/2 specifically when Windows 95, Windows NT and DOS have been around for a while? I won't argue for or against UNIX. I use UNIX. In fact, I run the UNIX forum on CompuServe, so that's an environment that I'm very comfortable with.

But if we're talking about Intel platform, mass desktop appeal, then the real issues are OS/2, Windows in one of its variants or DOS. I don't think anybody would argue that DOS is not exactly the best vehicle for graphic communications, or that one of the variants of Windows does a much better job.

What we get out of using OS/2 is something that you really don't begin to get in the Windows arena until you start considering Windows NT, and that takes significantly more resources to make it work. In fact, when we do the OS/2 demo on that thing, it's only running eight meg of memory and it's got a small hard disk and a 50MHz processor. So we're not talking about a speed demon by today's standards.

What I have done on my desktop system, which is a 486 DX2 66 with 16 meg of memory that is run concurrently, now I've got BIOS that supports multiple, more than two, COM ports simultaneously. That's a computer BIOS issue, it's not specifically a DOS, Windows or OS/2 issue. As long as the hardware provides for separate interrupts and separate I/O addresses, OS/2 will very nicely allow me to deal with connecting with the Internet and a 14.4 fax coming in at the same time that I've got another connection going to CompuServe, all without impacting other stuff that's going on in the system.

M: [inaudible]

David Moskowitz: Four, there are a total of four modems on this system, but this is all done with three separate modems. Dialing Advantage for the Internet, as an Internet provider, a 14.4 fax that was coming in from I don't know where. Actually, I do know — it was from my publisher; it was a 53 page fax of a chapter that they wanted us to proofread. I asked him to send it to me e-mail, and publishers think e-mail means fax.

I was also doing maintenance on the CompuServe forum at the same time that we were in the middle of trying to print some stuff for the next edition of the book and do other things. And as I said, all this on a 16 meg system. It works very, very nicely.

The other thing that you can do with OS/2, and this has been available for a while, is multiple virtual TCP/IP circuits. What that means is that over the same Internet connection, I can have a Telnet session running, an FTP session running, a Web session and an Archie session. Almost any one of the Internet tools or protocols can be in concurrent use without any problem.

Now, the Internet connection and the CompuServe connection are both 28.8 modems. The only thing that I am doing that is different — and we'll talk a little bit about it as we go through the hour — the only thing that I'm doing that is different is using [Raygen's] SIO drivers, instead of the standard COM drivers that come from OS/2. The [Raygen] SIO drivers are shareware. They cost something like under \$50 — and no, I don't work for [Raygen]. I've got no vested interest in any of the companies or issues that I'm going to be talking about today. What the SIO drivers allow us to do is get communications easily from all of the ports. The OS/2 COM drivers realistically don't support much more than about 57.6 or thereabouts.

So what that means is that in the one system, with all of this stuff going on concurrently, we can also have multiple TCP/IP sessions running through the same Internet gateway without impacting performance.

Now, there is an obvious difference between trying to deal with Internet, within limits. Graphic environments are responsible for selling faster processors, and more memory. The Internet is going to be responsible for selling faster modems. And 28.8, if you know that's the ultimate, we haven't begun to see the last of it.

The bottom line is that the limit here turns out not to be OS/2, but it turns out to be the Internet itself. How much can you pump down a 28.8 pathway? Obviously if I had a T-1 or

fractional T, I could do a whole lot more, and we've run OS/2 systems that are connected to a network that are dealing with T-1, doing the same type of stuff, but now dealing with it over a shared network port and a shared modem pool rather than having three separate modems. And again, in those instances, the actual impact on standard work is even less, because in many cases the network adapter handles a lot of the communications stuff for you, and it's coming in at a higher rate and the drivers are more efficient than standard COM drivers where you're looking at having to get a character out of a modem one character at a time.

The other thing that I happen to like about OS/2 is that it's reliable. It stays up. I have a little program that runs every time we boot OS/2 on the desktop system that doesn't run on the laptop systems because it doesn't do anything — the laptop just shuts off to recharge the battery, change the batteries, so that trying to keep track of how much up time I've had on a laptop doesn't make as much sense. But on a 486 DX 266 — when I left Philadelphia yesterday, the system had been up continuously, from the last re-boot, for 27 days and 14 hours. Why 27 days and 14 hours? Because once a month I re-boot the system whether I need it or not.

So, what's going on with OS/2 and the Internet? Why is it a platform that makes some semblance of sense? Warp shifts in two different flavors. There's Standard Warp, in which case you get the Bonus Pack, or there's WarpConnect, which also shifts with the Bonus Pack. But WarpConnect includes TCP/IP Version 3 from IBM, whereas the Bonus Pack is sort of an upgrade of TCP/IP Version 2. The Bonus Pack TCP/IP is designed for serial communication. The TCP/IP that comes with WarpConnect will handle either serial or network communication, so you pick the one that makes sense for you. From either one it doesn't make any difference, the base tools that are installed are pretty much the same.

You can use other providers to get to the Internet, and in fact I do. I use Advantis, I use CompuServe, I use LibertyNet and other providers in the Philadelphia area. When I'm on the road, depending on where I am, I make different choices; but we'll talk about that in a little bit.

There's also third-party tools available for FTP — *Newsreader*, *Gopher* mail, IRC and more, if you want them, so that you're not limited to the IBM tools. And if you're really convinced that *Netscape* or *Mosaic* or some other browser or other set of tools work, you can use Windows variants and Windows tools in OS/2. So if you're familiar with or prefer the *Netscape* interface capability, you can use that, although part of what *Netscape* does, at least in the 16-bit Windows arena — we just starting playing with the 32-bit version for Windows 95 and Windows NT — what it does in the 16-bit Windows arena is simulate threads. Threads are separate executable pads, so that you can have multiple parts of the same program in concurrent execution. In the Windows 16-bit arena, *Netscape* simulates that capability. In the 32-bit area, it actually should use it, but I don't have any personal experience with that yet, as I said.

What you get out of OS/2 is that same capability built in, and in fact you can specify the number of threads that you want the *Web Explorer* to create. Then what it will do in OS/2 is create effectively a virtual TCP/IP circuit for each one of those and download graphics and text concurrently. And now the speed with which stuff comes down depends upon the bandwidth that you get stuff moving through the pipe.

Now, some personal choices. As I said, this is part of what I do, but it's also stuff that you can consider as well.

If you're going to deal with IBM's TCP/IP in either flavor, either on the Bonus Pack or WarpConnect, part of what you can do is connect to the Internet through Advantis. I happen to use, for most of my travels, either Advantis or CompuServe, because they've got more worldwide nodes than anybody else. So the issue is that America Online is a nice service, but if I'm in Europe they don't have nodes that I can get to easily. The same thing is true of Japan, where both Advantis and CompuServe do. There are some areas of the country that America

Online, Genie, and Prodigy — well, not so much — but America Online and Genie have fewer nodes or not quite as reliable service as either Advantis or CompuServe. So because I depend on electronic mail and I travel a lot, I use those guys as providers.

Now, if you have Internet access through your own office and you can call back and deal with it that way, that still works. Basically, the way to pick one of these things is look for the highest-speed, most reliable, cheapest provider that happens to be wherever you are. One of the things that I've discovered is that Advantis has an 800-number and the fee for the 800-number — how many of you travel regularly? Have you ever been in hotels where they tell you the set-up charge for the phone call is a \$1.00 and then you get charged \$.50 a minute? It is cheaper for me to call the 800-number when there is no fee associated with the hotel, and come into Advantis with a 800-number, than it is to pay the hotel charges. So that's something that I keep in mind. Advantis has a global phone list that's updated regularly, and I'll show what it looks like in a little bit. Most in the U.S. are at 28.8.

Of the major services, CompuServe has the most national and international nodes. They have said that within the U.S., all of those will be 28.8 within the next three to six months. Worldwide, they'll be at 28.8 within a year.

So, because of the fact that time is money, I'm looking for the highest speed and the most reliable access. I've found in my personal experience that these two suit my needs better than anybody else. When I'm back in Philadelphia, it doesn't make any difference. I'll come in through LibertyNet, I'll come in through Net Access, I'll come in through Fish Pond or FishNet. Their FTP address or identifier is pond.com — they say everybody is fishing in a common pond. That's theirs; all I did is repeat it, I'm the messenger. I apologize.

The other thing, as I mentioned earlier, is I use [Raygen's] SIO drivers. That allows me to get a 115.2 connection, assuming that the modem is supported. Advantis does support compression, CompuServe doesn't, at least not at the same rate, so there have been times through Advantis where I've seen figures running close to this. Through CompuServe I rarely see more than the equivalent of about 30K to 33K.

Now the other thing to consider — how of many of you have tried to dial in to a 28.8 provider, only to discover that your modem needs to negotiate a 26.4 or a 22.2 rate or something like that? I see that a lot. That's significantly better, obviously, than 14.4. But about 80% of the time, I discover that the modems have negotiated a rate lower than the maximum 28.8 baud rate. That evidently turns out to be just line conditions and standard. Which means, if you will, the 28.8 isn't the limit — it's a theoretical maximum that maybe I'll see some day.

Travel problems in dealing with the Internet. How many of you have multiple e-mail services? I love it — I thought I was one of the few. If you have multiple e-mail services you probably have multiple phone books, you probably have to deal with hotel access. Sometimes I deal with modem-hostile hotels, and that's fun. Have you ever been in a hotel that has a digital system and they do not give you modem access? Or they'll put you in a modem access room, but they'll charge you an extra \$15.00 to \$20.00 a night for it? Ask before you get there.

Part of the problem when you're on the road, when you're trying to merge Internet data, obviously has to do with making stuff work. In the OS/2 area I tend to use a tool called *Linkwiz* from PCX Software. *Linkwiz* is like *Laplink* for DOS, only it allows me to get the file's level and it updates stuff as it needs to. I also can set up to make it do automatic backups.

The other thing that I travel with that has OS/2 driver is the [Brunel] *Zip Drives*. They're parallel port, they're light, compact, and they're a lot better than tape. And the other thing that we'll occasionally do is take stuff out of one service and re-mail on the other so that it shows up on a consistent place.

So [now let's get to the] technical stuff, which is probably why most of you are here anyway.

Getting started with OS/2 on the Internet is relatively simple. There are basically three steps. Now, don't misunderstand, I'm not trying to make light of this. Installing OS/2, like installing Windows 95 or installing NT or installing UNIX, I'd rather leave to somebody else than have to do it myself. Any time you start talking about more than three or four or five disks, then installation can be interesting. So if you can, deal with it by installing it by CD. Anybody here that does not have CD-ROM?

So, step number one, install OS/2. Then either install the Internet Access Kit, if you're dealing with Warp or WarpConnect's TCP/IP.

Once that much is done as step one, the next thing you want to do is register with Advantis, and as I said, I'm talking about Advantis because that's the simplest way that I found to get up and running on the Internet. There are cheaper providers, there are providers in your area. Anyone come from Youngstown, Ohio, or know anybody who does? Youngstown, Ohio, has a "freenet" for their residents, so that anybody that lives and pays taxes to the municipal authority of Youngstown, Ohio, has access to the Internet if they want it, because it's supported by their tax dollars. Certainly if you've got that type of capability then you're going to take a different path to get to the Internet, regardless of the platform that you're using. So, we're talking Advantis here because it's the easiest registration that I've found. It really is simple, and I'll walk you through it.

Once that much is done, you're up and running. If you're using another provider, if you have access to the Internet through another provider, setting up the other provider is different. At that point, what you're going to have to do is talk to the other provider and find out what steps they have or what you're going to have to do to connect to the other provider's application, if you will, so that it talks to their service from OS/2.

CompuServe, by way of an example, will tell you that if you want to use CompuServe as your provider, if you are already a CompuServe subscriber and want to keep everything in one basket, then they give you instructions. All you have to do, literally, is take it out of the file from CompuServe and paste it into the other provider's as a script, make the two or three changes that they suggest that you make to the other provider's icon settings, and you can be up and surfing through CompuServe in a matter of about five minutes, including the time that it takes to get the information from CompuServe. Now, having said that, if the network and communication is a little bit slow, it might take six or seven minutes, but we're not talking about a whole lot of time in most cases.

I'm assuming that everybody knows what a URL is, and since this is an Internet conference that's a probably correct assumption. In case you don't know, it's up there. A couple that you probably want to pay attention to, if you're looking at the Internet through an OS/2 resource: www.ibm.net is the home of Advantis, even if you're not using Advantis as your provider. Whether you're using CompuServe, Net Access, NETCOM or somebody else, if you're using OS/2 as a base in any of the tools you want to pay attention to this guy, because that will tell you if new stuff is around. They also provide some interesting resources and lots of pointers to Web locators, so it's a good resource to be aware of even if you're not using OS/2.

The other thing that you want to deal with is the difference between command line tools, like FTP, and PM tools for FTP. The PM tools provide drag-and-drop, so that if you see something in the remote directory that you want all you have to do is select the items and drag them to the local directory, which initiates a TCP/IP transfer or an FTP transfer.

Conversely, if you want to take stuff and upload to FTP, again you have to deal with drag-and-drop. If you're going to use the command line side, then you have to be aware of commands like BIN or ASCII, etc. You also need to be aware of things, if you want a progress indicator, that there's a hash command for command line TCP/IP that the drag-and-drop PM interfaces will do for you without the overhead, the associated overhead of the hash.

Other things that you can deal with: there's an Archie tool, etc. for OS/2. There's also, if you use IBM's FTP PM or FTP, there are some Net AC file tricks that you can play, including automatically adding the machine log-in and password in a Net RC file. It's an ASCII file.

Now, if you wanted to connect, for the sake of argument, to `walnutcreek.ftp.cdrom.com`, all you have to do from the command line is say `ftp.cdrom.com`. FTP will check the Net RC file and discover that you've got an entry so that you will not get prompted for user name and password. It will automatically supply it so that you don't have to keep typing that stuff. I don't know about you, but I suspect there are a lot of people that learned how to spell acronyms because of the Web.

Getting software updates. Again, if you're using the OS/2 tools, regardless of the provider that you're using, CompuServe — AOL, NETCOM, Net Access, you pick it — you can still use the OS/2 tools to get software updates. And you can also use FTP from `ftp.ibm.net` in the pub directory and then pick the component that you want to update. The way of updating third-party tools is obviously going to vary to some degree.

All right. Now, part of what we're going to do is a brief demo. If you have questions, please ask them. We'll take you through some of the desktop setup, what it takes to register the system, register and get running with Advantis. We'll take a brief look at the Web browser and some of the things you can do with it. A brief look at FTP — as I said, this is not connected, so these are demos.

Now, you know what they say about demos. Frank Baum, author of the *Wizard of Oz*, wrote about demos, "Pay no attention to the man behind the curtain." And obviously what we're trying to do along the way is answer your questions.

So, a couple of things just to consider. From *The Wall Street Journal*, "The change of these networks is generally the easiest, cheapest way for business to communicate electronically with the outside world." [That's] from *The Wall Street Journal* approximately a year ago. My way of rephrasing that is saying, "the Internet is the easiest way for you to pick up anything in the world, transplant it or transport it to your very own desktop."

And finally, this is something to consider: the only dumb question is the one that isn't asked. I also suggest — a friend of mine at NASA said, "You know what rocket science is?" And I said, "Well, I thought I did, but why don't you tell me." He said, "Rocket science results from asking questions — but the actual science itself, where's the rocket science? In the plumbing, in the electricity, in the chemical engineering and in all of the little tasks that go into putting a man on the moon. It only appears to be rocket science when you don't ask questions."

I think Arthur Clarke also put it well. He said, "Any sufficiently advanced technology is indistinguishable from magic."

Contact information if you like it, this will be on the CD as well. If any of you would like handouts or copies of the handouts, plus some additional material that's sort of text, write on your evaluation that you want handouts and we'll get those — hopefully before Comdex, but if not, right after Thanksgiving.

I can be reached at a couple of different e-mail addresses: `davidm2@ibm.net` or `dmoskowitz@cis.compuserve.com`. If you have CompuServe access, 76701,100. My Web page is partial but it will be up and running, and that's one of the things that will be up and running before Comdex, there's some limited stuff there.

[There's also] <http://www.cfsrex.com/unleash>, and phone number information is there. I have business cards as well. So much for the marketing stuff.

Now, let's deal with the high-tech video switcher, a relatively clean OS/2 desktop tool. What we have over here on this launch pad is a dialer. Now, this is the IBM Internet dialer. Normally, the first time that you run this what you'll see is something that says, "Do you want to register or are you already registered?" So once you get there, you open an account, open a

personal account and read the stuff that's there. By the way, I don't know anybody that really takes the time to do that. IBM has lots of lawyers, so they make sure.

Now the other stuff that we do — do this, fill in name, address — pardon me if I don't fill in my credit card type and number, or at least not a valid one. It does try and do some checking and obviously — let's do this, too. Let's see if can preclude some of this. I'm trying to short circuit this, but I really shouldn't, so let's do this and try... That's American Express. I'm not going to put my number in there.

The next thing that you see is a screen that asks you for choices for a user name. You give it three choices and then it says, "Do you want to connect or defer it?" On the fifth screen, push the button and you're up and running. What you end up with is something that looks like this.

And now enter your password, hit "enter" and you're up and surfing on the Internet. It really doesn't take more than about three minutes, if you type everything the way you're supposed to. If you try and short circuit it or give it an invalid card, as you saw, it does enough checking to know there are potential problems.

Now, what we have over here is, while I was typing the password it was looking for the modem, trying to do that on a separate thread. There is no modem that is connected to this system at this time, so obviously it's not going to work. But it would continue to try and deal with that, and once it gets through the modem it would try and make sure it has a connection. Then it would log on to Advantis, and then you get the thing that says you're up and running and surfing. Once that much is done, you can close this thing and just move it over.

We have a series of other things that we could do with the network; if we wanted to we could register an additional user or other users, so this takes us back down the same path that we had before. If we wanted to we could update the software.

Now, here it's asking if we want to connect. I'm going to say don't connect at the moment, in which case what would normally happen is that it would now go out to the Gopher site and fill in that list box that we saw. You pick the item that you want, click "install," and it will download it and then automatically install it. You don't have to do anything other than select, click and install. And while that is going on you can still do other stuff if you wanted to. You can also look at the *Web Explorer*.

Now, if you'll notice, when I had that — let me do this very quickly for a moment. If you'll look down at the bottom you'll see that there's a percentage of the document that has been downloaded and then there's parts of the article that can be downloaded on multiple threads. Now, at 8 megs of memory I don't have more than 4 threads, but I can have — and in fact do on the desktop sitting back in the office — 8 different threads running. What that means is that I have 8 different virtual circuits downloading different parts of the document concurrently.

So if you've got a document with lots of graphics, with each graphic item what the *Web Explorer* does is say, "here's the HTTP of the document," and as it accommodates tags that say "image source" it goes and it starts another thread to go get that image source while it's downloading the document. So what we see looks considerably faster. That was something that Netscape started doing. That's one of the reasons why the Netscape browser has the appeal, because it tries to do some of that as well. The *Web Explorer* actually does it.

Now, part of what we can do is look at some local stuff, and if you do that and just give it a directory then the *Web Explorer* says, "all right, I'll give you a directory as if it was FTP." Now again, this is on the local machine. Notice that what I'm doing down at the bottom; I've got this set up so that I'm showing the current URL here and the link URL at the bottom, so that as I move that — can you see that that's changing, even though you may not be able to read it? Yes, no, maybe?

So now if we select this guy, notice the way graphics come in. You actually see them as they are displayed. That is the way it works, whether you're dealing with it as local files or through the Net. Now, I don't have this entire document set up to deal with it, but part of what we got — if I had left this for the Internet, each one of these things is a button, but if we wanted to we could go get another.

Part of what I'm trying to illustrate with this is a couple of things. Number one, the *Web Explorer* caches documents, so that — notice, I got this one faster the second time; now, yes, it's coming off a local machine, but the key is that it still caches the documents and images. How much of a cache do you have on an 8 meg machine? I'm not going to cache a whole lot. On a 16 meg machine, I'll cache a little bit more. There are times when I use a laptop that has 40 megs on a DX4 100, and if I'm doing demos with that system then I'll cache even more because I want the performance. But the key is that that type of caching is done in the *Web Explorer*, and it makes things significantly easier.

Now, one of the other things that IBM provides is information for the subscriber network. Notice again that you can see the difference in how the stuff is colored. You can change all that if you want to, and in fact, if we wanted to we could come up here to configure and say colors — this is not one that I would suggest, but I'm doing it to make a point. But we could make the background that way, links, we could turn black text into purple and visited links gray. If you really want to you can deal with that as well.

The *Web Explorer* also supports animated icons, so if somebody has their own icon that they want to give you, this guy up here can be changed. It supports the HTML 3 extensions, so if you've got a background that will show up as well without any problem. It also supports the HTML 3 attributes for centering and other stuff.

Quick list. We can add the current document or more; I don't have any added this way because in part, part of what I can also do with the *Web Explorer* is deal with drag-and-drop. So I could take this guy, if I were connected — that's David Barnes' favorite shareware — and drop it. Because we don't have a modem connection, you see <http://www.os2bbs.com>. David Barnes has been abandoned. I can also save URLs using drag-and-drop, so that if this were a file, at the bottom it says "preparing URL for dragging." And now I've saved it.

If I were to restart the *Web Explorer* from scratch, so that it's not running...

[Tape change]

David Moskowitz: I don't remember the complete list, I'm sorry. It comes with the Internet Access Kit, comes with multimedia viewers it supports, standard wave, which comes with OS/2 AU files.

M: [inaudible]

David Moskowitz: Yes, MPEG, TIFF, GIF; I don't believe there's PCX support — yes there is, as a matter of fact.

M: [inaudible]

David Moskowitz: I'm sorry?

M: [inaudible]

David Moskowitz: I don't know off the top of my head. I know it supports standard Apple, IBM.

Okay, what's here? Editor for HTML source, GIF, JPEG, IEF, TIFF, bitmap, RAS, portable any map, MPEG, QuickTime, AVI, AVS, CGI, AU and SND for audio format. AIF, AIFF, AIFC — there's a few of them.

Now in some cases, IBM doesn't supply viewers for all of them. I was trying to give you the list of things that IBM supplied. Most of the sound files that are there — I don't think real audio is there yet, but I don't really know to be sure. I haven't come across too many real audio sites on the Web yet. So a lot of what I can tell you is based upon my personal experience, and while I do a lot of surfing, I'm one person. Anyone here really feel that they're an expert about what's on the Web? Okay, one person. What do you do for a living?

M: [inaudible]

David Moskowitz: Part of what I do for a living is deal with the Internet. A lot of it has to do with helping our clients understand how to use the Internet and be profitable, so that limits the amount of time that we have. We do have one person that does a whole lot of Web surfing, but that's what it takes to be an expert at it.

Part of what we have done with OS/2, by the way, very successfully with beta software, is use *EM Bone*. How many of you are familiar with *EM Bone*? *EM Bone* is videocast on the network, on the Internet, and it's real-time video. We've found very good use for *EM Bone* in an OS/2 environment. We tried beta software for Windows 95. Windows 3.1 and its derivatives don't really handle it. Windows 95 has problems. The best two Intel-type systems to handle *EM Bone* graphics today — and I'm going to make the assumption that it's within limits, probably true to some degree for real audio — are NT and OS/2. UNIX will obviously handle *EM Bone* very well. Like I said, I'm not trying to take anything from away from the UNIX environment. I spend a lot of time using it myself.

But the key is that this is the list of supported browsers that you can add in, including, for those of you who like UNIX, TAR — or I think I saw in here the PKZIP format. The reason that I started this...

M: Since a program didn't come up under that [inaudible], that means it's not included?

David Moskowitz: I did not configure this one for it, because on 8 meg I just did not take the time to do that. And for ZIP files, normally I wouldn't want a viewer or something like it. I want to download it directly to my system.

M: I'm just curious, like [inaudible] viewers that are set up in OS/2, will that viewer pre-configure [inaudible], pre-configure all viewers at the basic [inaudible]?

David Moskowitz: Yes. I don't know if any of them will show up here — there's one, so yes. So you can see the stuff showing up. You may not be able to read what's there, but you can see that there is some stuff in the program area. Those are the default viewers that are set up.

Now, I don't know if you watched what I did, but to get this page back all I did was drop the URL and just drag-and-drop it. Because of the fact that OS/2 supports the work place shell as a COM interface and *Web Explorer* participates in that, you've got full drag-and-drop capability. Not only can I drag the current URL that I'm looking at to a folder or the desktop, I can also drag the document. I can drag a GIF image if I want to, or a graphic image. So if I wanted to take this graphic and put it on my desktop, it's now sitting there as a GIF file. I could drop it back on the viewer if I wanted, using the *Web Explorer* as a viewer to actually view the

bitmap, with complete drag-and-drop capability. In any of the viewers that are supported I could either double click on the item on the desktop or drag it back to the *Web Explorer* as a viewer.

Other things that are supported: if I deal with FTP PM, and I don't want to connect, part of what I would do is fill in the host URL minus the FTP adjuster locator, the user ID and the password and again, if I have a Net RC file for OS/2 FTP PM, all I have to do is fill in the host and it will grab the user name and password from the Net RC file.

We're not connected, so we won't see anything here. It can't get to the host, so it's obviously not going to go anywhere, but what we would next see is this type of interface. What we'd see down here in this area are the remote files. Again, to transfer something all I have to do is drag-and-drop it. That would automatically send it. Going the other way, if there were files in this list, I could drag them and drop them going the other way as well.

M: Does your system support VRML [inaudible]?

David Moskowitz: I'm sorry?

M: Does your system support VRML [inaudible]?

David Moskowitz: Does my system?

M: Or [inaudible]?

David Moskowitz: If they're available, certainly.

Other tools. Now, what I'm showing you comes with OS/2. There are third-party tools that replace all of these, so you can deal with third-party tools if you want to. Gopher is the same way, and again you'd see the Gopher menu that's there, and you could click on that or deal with a series of menus to open up the Gopher if you wanted to.

M: Does it cost anything?

David Moskowitz: It's free.

M: [inaudible]

David Moskowitz: It comes with, on the Bonus Pack, with OS/2 Warp or WarpConnect. And you don't need the Bonus Pack with WarpConnect, except for the multimedia viewers; but it's included in the base package. So I don't know what the street price is of OS/2 these days, but my guess is it's probably under \$100 for Warp and probably about \$120 to \$140, somewhere in there, for WarpConnect — but it includes TCP/IP. In fact, one of the other things you get with WarpConnect, having nothing to do with the Internet, which is why I didn't mention it, are things like peer-to-peer networking, including the ability to share modems in a peer-to-peer network, sharing printers on a LAN distance server, if you're interested.

If you've got a mainframe site or somewhere that's running a LAN distance server you can connect to the other network and have access to the entire network remotely; or have just a peer-to-peer arrangement where two LAN distance clients can talk to each other and stay within the same machine, without getting out of the network. So depending what you're doing, WarpConnect makes some semblance of sense.

As long as I've got a few minutes, how many of you saw the *New York Times* article around August 1st, in which Gerstner was supposedly quoted as saying that IBM is abandoning the desktop? Anybody?

I mean, the bottom line is that it was not handled very well, either by the *New York Times* or by IBM. The guy that wrote the article — my cousin is a securities analyst and knows the author of the article — the author was not present at Gerstner's speech, so I'm not sure where all of the information came from. But the bottom line was that the author wasn't present at the speech.

The other issue is that if you look at what IBM is doing and where they're going, it's not going to be too long before almost every single computer, every personal computer, is connected to something. It's either going to be a network — that we think of as a LAN in an office environment — or dial-in to an office network, because a whole lot of companies are now allowing people to work from home, or they're dealing with office sharing as a way of cutting down on real estate costs. Or people are going to be connected to some other network, like a CompuServe or an AOL or a Genie, so that's it not going to be too long before all most all of us are connected.

IBM's Networking System Division said it very distinctly about a week and a half ago at Colorado OS/2, which is, in my opinion, a premiere developers' conference for OS/2 developers. What they said is — and it's the best answer and it's the answer that IBM had given, and the response that IBM had given back in August — they said the reality is that it's not going to be too long before everybody is connected, and what IBM is trying to do is deliver platforms that work in a connected world.

Well, the question was asked, "When you said everybody is connected, do you mean everybody in an office or everybody at home?" They said with cable companies, telephone companies, everybody competing to try and deliver service to all of the subscribers, both home and business alike, we want to be a player in that area.

So if you view what Gerstner said about networks in that context, it's not a question of OS/2 abandoning the desktop, it's a question of recognizing the realities, which is what I would personally like to see IBM do.

To emphasize the point, a couple of things. Number one, drop the current Warp package. Then take WarpConnect, drop the price of WarpConnect so that it's in the same basic price range. Obviously it includes a little bit more so it would cost a little bit more, but have the price for WarpConnect be close to what Warp is today. One product without the confusion; because what we have today is Warp with OS/2 and without, WarpConnect with OS/2 and without, so IBM is now supporting four different products called Warp. I'd like to see it be effectively one. Then the only question that you have to ask is, do you have Microsoft Windows, or do you want IBM's version of Microsoft Windows? That would make the message a lot clearer, particularly if it's priced so that it can be purchased both by business and by home. That, I think, would make the message that IBM is trying to deliver a lot clearer.

Having said that, I don't work for IBM. The requirement of my company is that we are not allowed to own stock in any of the companies that we either have as clients or might have as clients. We do not have fiduciary interests in IBM or any of the other companies that I've talked about with you today; so it's not a matter of conflict of interest in trying to promote something that's going to make us money, because that just isn't the case.

IBM has perception problems, and I'd be lying if I told you otherwise. How do you deal with the perception problem? Don't talk about it, do it — it's that simple.

Are there any questions?

M: When you were explaining the [inaudible].

David Moskowitz: The default value is four. You get four threads if you don't do anything. If you wanted to change that, then what you would do is come up to the *Web Explorer* icon, open its settings — where I have a “q” here that says, “Don't give me the message you're about to start the *Web Explorer*, and don't ask me whether I'm sure if I want that, I want to end.” In other words, “quiet.” The next parameter that I would add would be if I wanted eight threads, and then when the *Web Explorer* opens you'd have that number of threads.

M: [inaudible]

David Moskowitz: Actually, if you look at it — I'm not going to tell you it's intuitively obvious, that's a phrase that I have grown to abhor — but the *Web Explorer*, if we bring it back up, for the most part it's configured. If you add multimedia browsers those things are automatically added by “install” so that you don't have to worry about it. For the most part, the way that it comes is like this, without the current URL. Then if you look at the bottom, as I track the mouse over the buttons there's help for each of the buttons.

But for the most part, in what we've seen in talking and working with people, it takes them anywhere from 10 to 15 minutes to an hour and they're up and running without realizing that they're surfing the Net. And particularly with the PM interface.

If you're talking about a command line interface, MGET, binhash prompt, and the rest of that stuff are enough to drive anybody nuts. And if somebody has to learn a command line interface to deal with the Internet the chances are very good that they will find other things to do with their time. That's like telling people that UNIX has the best interface in the world. Now you know better than to try to make any sense out of that.

And oh, by the way, don't forget to put the pipes in where they belong. I mean, that's one of the reasons that UNIX does not have a larger appeal. I don't know about you but GREP never made a whole lot of sense to most people, even though I know it's “generalized regular expression pacer.”

If your dealing with a GUI, depending on the care that was done with the GUI, for the most part, if you look at and if you take a few minutes while I'm doing this, we'll do a drawing for a book and then I'll let the next speaker set up.

Once we get something in here it's a matter of selecting it from the list and then pushing the “install” button. The user doesn't have to know anything else, they don't have to know how to deal with installing or putting things in the right directory.

M: It's pretty obvious.

David Moskowitz: It is, and with an FTP file you get “get” or “put” and the local, whichever file you have highlighted — they've tried to build some intelligence in to it so if you've got a file highlighted under a local directory under “file,” the menu item that you see says “put.” And if you've got something highlighted in the remote directory, the file item that you see is “get.” If you've got both highlighted, things could get interesting. There are third-party tools that frankly, in some cases, have done a better job, both for the *Newsreader* and FTP.

But the key is what you're looking at is a graphical environment that buries some of the Internet complexity. Remember — how many of you have used the Internet for two or three years? And if you remember before there were graphics stuff, there was command line, and everything you did, Telnet, FTP, Archie, WAIS, was all command line driven. There was a different set of commands and a different set of syntax for each one. You really understood that

the Internet was a process that was designed by committee, because every single one of these things had a different way of dealing with it.

Not only that, if you took it one step further, you could go to different Archie sites, WAIS sites, etc., and the way that the information was organized was different. So the elliptical nature of the Internet shows.

Any other questions? If you would take your sheets and pass them one way or another, and he'll get some and I'll get some and we'll do a drawing and give away a book.

Thank you very much, I appreciate your time and effort. Was this helpful for you, I hope? Good. And again, thank you very much.

INTERNET TECHNICAL THE “HOSTED” WEB SITE: WHAT YOU NEED TO KNOW

MODERATOR
Ivan Pope
Webmedia

SPEAKER
Joe Peck
Product Manager, Internet Server Services, Digital Express Group

Joe Peck: ...it doesn't have to be on your computer. It can be on any computer that's up on the Net. The only real requirement is that the computer needs to be up 24 hours a day, 365 days a year. And it needs to have good conductivity so that you have adequate response to your site. And then the other thing is, you want to make sure it's got adequate system performance; you don't want to be putting it on an underpowered machine. So really, I think those are the only three requirements of having a Web site. And based on that, there are a lot of computers out on the Internet that fulfill those requirements.

You see a lot of sites that are on computers at universities, but typically they aren't taking paying customers. So what you want to do is find the best computer on the Internet to put your Web site onto. From my perspective, when I was looking at putting up a Web site initially, when I quit my job and tried to start a Web company — how many of you people here have done that? At least one, yeah.

I went to an Internet provider because they had the best computer for me to put [the Web site on]. I'll talk about it in a while, why the Internet providers, in my opinion, are the best place to put it. But at that time, they didn't want to do it, they weren't in that business. Nowadays, a lot of Internet providers are in that business.

I should mention I work for an Internet provider and yes, we do this stuff. I'll try to be unbiased about the whole thing here as much as I can.

You have choices. You could put the computer on your site on your own computer, on your own network, provided you have Internet conductivity, or you can put it off-site at somebody else's computer. You know, a lot of people, even though they have conductivity to their own place, are still looking at putting it somewhere else.

Some reasons you might want to do that would have to do with the fact that a Web site may bog down your circuit. You may only have a 56K line, or even a T-1 circuit to your site, and a lot of the traffic to a Web site can bog down the conductivity for the other purposes you're using that connection for. So for example, a company like Digital Equipment Corporation — or let's not use that as an example, I used to work there. A lot of companies may have a 56K line, and if they put a Web site up, all of a sudden 90% of their bandwidth is being eaten up by their Web site. They may want to look at putting their Web site off-site at some other place so that their bandwidth isn't being used up by the site.

The other reason to put it off-site is that your Web provider, your Web hosting site, may have a more reliable connection than you have. They may have a 24-hour support staff, or they may have redundant circuits — in case one circuit goes down, they've got a backup circuit. That sort of thing. Or maybe you just shut your computer off. I've seen systems people do that; they go home at five, and they shut off the router. It's true. So you may not have the most reliable circuit or it's not going to be up 24 hours a day — you can't count on it. So you may want to look at putting it someplace that is.

And by reliability you want to factor in things like power backup, a 24-hour network operation center keeping a watch on things, that sort of thing.

The other thing that Web hosting sites may have is better network support personnel, or a better network support infrastructure where they've got an automatic trouble-ticketing system, and they've got tools to monitor the systems to make sure they're always available. That sort of thing that you may not have in place.

A lot of people don't want to go out and hire an administrator to run their Web site when they can just pay somebody else to do the work, and typically those people are more experienced at systems administration and doing backups, all that sort of stuff. I'll talk a bit about that later.

There are also security advantages. A lot of people see a Web site as a high-visibility target, and they don't want to put that at their own place; they want to put it somewhere else so that at their own site, if the Web server is compromised their own site isn't compromised, because the Web server isn't even there. We actually hosted a three-letter agency for the government; we had it running on one of our servers because they didn't want to put it at their own place. It's the kind of thing that you can put your Web server off your site, and that way if somebody breaks in there, so what? They're not inside your network.

And then you may be able to get more Web expertise at the provider's site, too, because a lot of these folks are doing this — they're keeping abreast of the latest technology and they can let you know that yes, we've got this capability now; whether it's real audio, or *Java*, or some new database engine — that sort of stuff that a lot of customers just aren't aware of.

So those are some of the reasons to look at putting it off-site. But I haven't yet talked about who's doing the hosting. Who's offering these services? And why is one better than another?

I see three categories of companies that have gotten into this business. The first one is the start-up Web development company — four people go off, or even one, and they get a 56K line to their garage or to some small office, and they put up a couple computers and start arranging space on it. Six months ago they were running the Web server for their department at the university, and now they're developing Web sites for people, and they're hosting the site as well. Typically, in this case they've got expertise in developing the Web sites. They may have a lot of Mac skills and graphic skills. Almost always, they don't have the network infrastructure, they don't have redundant circuits, they don't have a 24-hour support desk with somebody on-site. They may not even have spare hardware in case the disk crashes, or something like that.

What I think is the worst — I don't want to denigrate these folks because a lot of them do really good work in developing the site, that's why you see the split as being nice — you can have folks like this develop the sites but put it somewhere else, because most of these folks don't have a clue about network security.

Whenever I give this talk, one of my favorite scenarios is when — how many of you were around when the Internet worm happened back in, I think it was '89? The worm broke into one computer, found out what other computers knew about, and branched out from there and just spread like wildfire. I could see somebody modifying a Webcrawler that crawls around and follows URLs. They could modify the crawler and toss in a break-in tool that crawls around the Web, breaking into as many sites as it can and replacing all the GIFs it finds, all the in-line sources. I think that'll happen. I used to say that 95% of the sites were vulnerable; I think it's a bit lower now. But a lot of sites just could be broken into very quickly by someone who knew what they were doing, because a lot of folks just don't have any clue about network security.

So other folks are offering service or that have gotten into this business of "We'll rent you space on our server or at our site." It's never consulting companies; they typically are people that have gone and they already have connectivity to their site, maybe a T-1 line or a 56K line, and they know how to run servers. So they can put a couple extra computers in there and start renting space. They typically have better system administration skills than the HTML

development companies that have gotten into the business, so they're more likely to have a secure computer, and be less vulnerable to break-ins.

But the things they tend to lack would be the 24-hour support, because there's not usually somebody there 24 hours — although if they're in the business a lot of them do carry pagers around, because they're doing that for the customers they're supporting network-wise as well. They are never consulting customers, but they don't tend to have the network infrastructure you'd want to have, with redundant circuits and power backup and that sort of thing. But at least they know how to run systems so it's less likely to be broken into.

The next category I see would be the Internet providers, because they're already running networks, they are already running computers, they have the bandwidth. It's nothing to them to put another computer at their backbone site, their point of presence. The nice thing about that is they usually have redundant circuits — if one goes down, they've got plenty more that the traffic will just flow over transparently, and you don't know that a circuit has gone down. We actually had a T-3 circuit go down, and all the traffic went over another T-3 and nobody noticed. So that's nice.

Power backup — usually they have uninterrupted power supplies. If the power is out for five or ten minutes, there is an array of car batteries, basically. Or if they're really into this they'll have a nice big power generator, a diesel generator. With a UPS, an uninterrupted power supply, that'll only last you five or ten or fifteen minutes, depending on how much you're trying to power. So it's nice for the power surges and for brief power outages, but it won't last for an hour or two or a day. So the ones that are really into this have the big power generator and they can keep the stuff going forever.

Internet providers typically have a heavy focus on network security because they've had people try to break into their sites before. What usually happens is they end up working with Web developers, so they may say, "Yes, we'll develop your site for you, we'll do the whole thing for you," but usually they're farming out the Web development, the site development of the content. Or they may say outright: "Yes, we just farm it out, and this is the developer we recommend or we work with," or whatever.

One thing to note is if you go to Yahoo and look for an Internet presence provider — what is a presence provider? There is confusion as to whether that's an Internet service provider that's going to give you conductivity, or an Internet presence provider that's going to develop your content for your Web site, or a company that's going to host your Web site. So you want to distinguish between the two terms: Internet presence provider and Internet service provider, service provider being the one that just provides conductivity.

Any questions yet? Am I going too fast or slow or along the right vein?
Okay, I'll get into this just a little bit more.

One thing to note is that not all Internet service providers are equal. Just anybody nowadays can go out and get a 56K circuit, which is not much more than — it's only twice as fast as your dial-up modems, your 28.8 modems. They can get a 56K circuit, put in a Sun server and a rack of modems, and they start signing up customers — they're an Internet provider. And that's why we have, I think, about 2,000 Internet providers in the States now, last count I saw. We have 60 down in the Washington, D.C., area where I live. And so a lot of people say they're Internet providers, but there's a wide range of those.

So the things that distinguish the Internet providers from each other would be the amount of bandwidth they have; how fast their circuits are; the support — it really ranges from nonexistent up to 24 hours that you can get a human being on the phone on-site. We had a salesperson who was competing with some hosting service, and so I said, "I'll call him up for rates and compare," and I didn't get an answer on the phone — it rang and rang and rang. And

then I noticed that their address was a post office box, and so that right there convinced the customer not to go with them.

Support is a really big issue. If your site goes down, or if you have problems getting to the site so that you can update the content, you definitely need support. Bandwidth and support, I think, are the two biggest issues.

Conductivity. When I say network infrastructure, there is bandwidth as far as how fast the circuits are, but conductivity is whether the circuits are redundant or not. One circuit going down should not drop your site; there should be a secondary and even a tertiary circuit so that your site is always reachable, even if a circuit goes down.

Another thing about Internet providers is that a lot of times they'll oversell their bandwidth. They'll get a T-1 line to their network, and they'll sell T-1 lines to their customer — you know, eight, ten T-1 lines sold — and so all eight of those T-1 lines are being carried over the Internet provider as one T-1 line. That degrades the performance getting to your Web site if you're one of those customers. There's a case I know of where there was a provider that had eight T-1 lines to one T-1, and there was a Web hosting service who was one of their T-1 customers. So that's one thing you want to look at. How much are they overselling their lines? Everybody in the business is overselling it to some extent.

How many have heard of the network access points? This one guy keeps raising his hand.

I think I have a picture right now, but the — I said there was 2,000 providers out there. If you're a customer of one, how do you get to a computer that's at another provider's site? Or if you're on America Online, how do you get to a Web site somewhere else? Basically these networks interconnect at certain places, and those are the network access points. The one some of you may be familiar with is called the KIX, the Commercial Internet Exchange. That was where initially there were bilateral agreements where one provider would hand a circuit over to another provider so their customers could get to each other.

And then there was a consortium, the Commercial Internet Exchange, where a lot of the providers ran circuits down to one place and connected together at that one point. That was one of the first network access points, out in Santa Clara. And now the main one is the [inaudible], the Metropolitan [inaudible] Net, it's actually fiber now, but it's still called the [inaudible]. That's in Washington, D.C., and that's where the major providers connect in with T-3 circuits or higher-speed circuits.

And so your Web site may be quite a ways away from that interconnection point, which means that all the people coming from those other networks then have to traverse a longer path to get down to your site. So you want to be as close to that interconnection point as you can with your Web site. Down on the right you could put your Web site, you could put on your own network on one of your own computers, but your connection may range from 2400 baud up to T-1 speeds. Physically, most people don't have greater than T-1 these days yet.

Or you may go with a Web hosting service down on the left corner, and they may have a 56K line all the way up to T-1. Some of them have — no, I haven't heard of any having anything higher than that. But you notice that there is no redundancy there — if that circuit goes down, your site is down.

You may go with a small Internet provider that's got a 56K line or T-1 line, or somewhere in between that, but they don't connect directly into those network interconnect points. They get their service from a larger provider, and that provider may get a [inaudible] activity from another provider. And so you may be quite a ways down the chain. At each point there is bandwidth overselling going on, too, so you want to be at a place that has redundant circuits and high-speed circuits, and is close to the interconnect point. But I think that's as technical as I want to get on that, because that's really delving down in there.

Anyway, getting away from the bandwidth stuff — really, in my opinion, bandwidth is one of the key issues, but nowadays a lot of people care about other things.

Pricing structure is a big one, and I'll talk about that a bit. How loaded the server is — if you're paying to put your content onto a computer, how loaded down is that computer with other things, other customers, possibly? Also what is the server platform?

Do we have any folks with their Web sites on an NT server?

Most people are on a UNIX system. Some people want to be on an NT server because their database is in NT, and they have some application on NT and so they want to stay with that. So you have to look at things like the operating system.

The hardware — what capacity is on the server? How many megabytes of space do you have on the server? That sort of thing is important. How much RAM there is on the server is going to affect its performance as well. And whether you can upgrade — as your site grows, are you going to be able to add more disk space to it? And what the cost is of doing an upgrade?

How your URL looks — is it going to be www.yourdomain.com? Or is it going to be www.provider.com/yourcompany? I'll talk about that in a second. But again, support consideration is getting to be larger and larger, because if the server goes down you want to make sure you can get somebody on the phone who can bring it back up. If you want to add an account, or if you have to upload new data to the system, you want to be able to do that.

And security, in my mind, is a big one. I was talking to somebody from the Boy Scouts at the national level, and the experience they've had with regional Boy Scout affiliations going on-line with Web sites was that people would break into the site and change the content. The national organization is not on the Web yet, and won't be until they figure out how to make it secure. I think that's interesting that the Boy Scouts would be broken into.

Access to the server and control of it [is an important consideration]. When I talk about access, that means you have access to the directory where you can put CGI programs, where you would want to put programs to process Web forms — that's the common gate where you interface. And some providers may not let you have access to that for various reasons, because then you're actually running your programs on the provider's system, and depending on how you wrote the program you may cause performance problems on the server or you may even bring it down if the program is written poorly. And if there are several other customers also sharing the same server, so you are going to basically hose over everybody else. A lot of times the provider will say, "Well, you can't put programs on the server," or, "You can use this library that we've developed," or "Give us your program, we'll look through the code and make sure it's okay, and if it passes muster then yes, you can use it." So that's one of the problems with a shared server that I'll talk about in a bit.

Server capabilities — things like whether you have a database engine on the server, so you can put your [inaudible] database on there, or if there's a search engine available as well. A lot of times the server is just bare bones and you can just put [inaudible] on there, straight files, and you don't have the interactive capabilities. You don't have the necessary tools to do the interactive stuff. So things like the programming environment... Most of your CGI programs that do the foreign processing are written — actually they're usually written in [inaudible] or C, or another language called "Tickle." And so you want those programming environments or those interpretive [elements] available on the system. And you may want *Java* on the system as well.

Who's doing anything with *Java*? Anybody? A few. Anything interesting you can talk about? Not yet.

The last thing on bandwidth — I think I've addressed that enough. Bandwidth, I'd say, is most crucial, and redundancy is critical — both in the circuits and in the power. And then again, how far you are from those network access points.

Actually, I was talking to somebody on the way in and he said that there was a hosting site that somebody was on, and they were at the end of a T-1 line and that hosting service then took on *Penthouse* magazine's site as a customer. And this other customer was very upset, because now all of a sudden nobody could get through to their site at all. That's what happens, so that's the consideration to worry about. And here I mentioned, again, bandwidth overselling, so I won't go into that any more.

Pricing structure is the one that I think most people that are having to pay for this are concerned about. I see that there are three or four pricing structures that are out there. And let me know if there are any I miss here, because I'd be interested

I've seen usage-based pricing. That initially was the most common, and that's where you would be charged based on the number of hits that your site was getting, the number of accesses to the site. People have backed away from that, and now they're saying they will charge for the number of megabytes transferred off the site per month, and they'll give a range. But again, that's usage-based, and what they're really saying is, "Well, you're bogging down our network connection, our circuits, and if you have too much traffic to your site we're going to have to put in more conductivity, we'll have to put in another T-1 circuit or we'll have to upgrade to a T-3 or something." And so they're charging you based on how much you're using their bandwidth, their network.

And then there is content-based pricing, which is really interesting. I only know of one provider doing this exclusively, and they're trying to say: "We don't charge you for usage, so we'll charge you this way instead." And this company is charging based on the number of files you have. Each file will cost you \$50 per month, or \$5 per month if it's a small file. And not only that, they go beyond that and they say, "Well, if you have a hyperlink in your file, we'll charge you \$5 for that, too — \$5 for every hyperlink." And what's really strange is they say, "If it's a hyperlink to your own file on your own site, it's so much; if it's a hyperlink to some other site, we'll still charge you for it at a different rate."

That, to me, is just completely insane because to the person running the site it is just another string of text in the file; it doesn't affect that site at all. But they're actually charging for hyperlinks in addition to a base floor price. So, yeah, they're not charging for usage, but they get you some other way.

The way a lot of places are charging is actually based on the capacity of the system. So they say, "We'll charge you so much for 25 megabytes on the server; or if you want a Sparc 2, it's this much; if you want a Sparc 20, it's a lot more. And so it's basically things like how much disk space, how much RAM is in the system and how powerful the system is. But typically the biggest one is usually disk space you've taken up.

And then a lot of people will combine these and they'll say, "So much for this much space, and then we'll also charge you based on how much usage to the site as well."

Has anybody seen any other pricing structures? No? Okay.

I think really that those are about it. Now, with usage-based, the problem with that is that it's hard to forecast. If you're having to pay for the system and you want to budget for it and put it in your yearly budget, let's say it's going to cost this much; well, you don't know how much traffic your Web site is going to get, so how do you put that in the budget or a forecast? You mark in the maximum number, I guess.

And worse than that is that there are robots out there, these indices like *Lycos* and *Yahoo*, and things like that, search engines. A lot of them are Webcrawlers that go out and explore the web and follow links and find as many pages as they can, automatically — they're robots. And while that means that's more traffic that also means they're pulling data off of your site, and that's driving up your usage. And yet all it's doing is possibly building an index, and hopefully it's one that people use.

I don't know how many robots are out there nowadays, because all these graduate students are looking for cool things to do at school, and they're writing robots. I'm on the robot's mailing list, and they're doing some strange things. You can actually put a file in your content, in one of your directories, that says "robots go away." So ask your Web developer about that.

How many have heard about that robot.text? Use it judiciously because, yes, you do want to end up in a lot of these indices but you don't need them canvassing your whole site.

What I think is most interesting about usage pricing is that, let's say you have somebody who gets mad at you, and they know that you have a Web site, and maybe they just guess that you're being charged per traffic. They could easily write a program that just keeps pounding on your Web site. All of a sudden your usage is again up to the maximum price. That might be a vindictive ex-employee, an irate customer, maybe somebody who's trying to do what's called a "denial of service" attack to your site, where they're just pounding on it so much that nobody else can get in there. And, yes, people do that. I would never [do that].

I think what's most interesting is that maybe it's the provider's competitor, which I would never do. But it's occurred to me that it would be very easy to do that. We could sit there and pound on some of these other hosting sites, and then call up their customers and say, "Well, we have flat-rate pricing." But, no, I'm too ethical for that. So that's something to consider in the pricing structure.

I mentioned the content-based pricing, and I just see that it's a feeble marketing attempt to say they don't do usage-based pricing. And to me, it's really feeble, because they're charging for hyperlinks to other sites, and that has zero impact on the server. It's just amazing.

And the other thing about that is, how many of you have sites that have shrunk in size over time? How many have grown in size and added more content? All your hands, yeah.

These sites grow, and you want to add more to it, and you may want to put a library — maybe you want to create an index of things that are of interest to your customers. Well, if you're being charged for every hyperlink or you're being charged for each little icon, that red ball next to the thing, or whatever, yes, that's a separate file and you'd be charged for that. So it discourages you from enlarging your site or creating more content on it, because it's going to affect how much it costs you.

So capacity pricing — the thing on that is to make [inaudible] make sure you can add capacity as needed. And that the upgrade cost isn't astronomical; the nice thing is that it's very easy to budget if it's flat rate.

Any questions on that one?

Okay, aside from the pricing structure, the server itself — we're going to look at the capacity of the server and what they're using it for. The big thing is how many customers are sharing the same server, because if you're sharing a site with *Penthouse* magazine your site is going to be inhibited as to the performance of people being able to get to your pages, because the server is so busy handing out pages for this other customer.

I've seen this. This friend of mine had a Web site he was paying to have hosted. He was getting 3,000 hits a day, which is trivial, it's nothing, and yet there were times when people would connect to his site and get "server too busy" error, "try again later." What that was telling them is was that the server is too busy because there's 80 other customers on that same server, and some of them are busier than his. So you want to look at that because, I think, initially when providers get started they may only have three or four or five or ten customers on the same server, and the server performance still looks okay, but as it grows... I saw one site that had 120 customers on one computer, and yeah, let's hope they're all low volume, low traffic. I suppose what you could do is ask the provider, "Well, what's the maximum CPU load going to be before you start putting customers off on separate boxes?"

Oh, this is funny, too. I saw one provider that says, "Yes, we have dedicated Web servers." What they're saying is, "Yes, these computers here are just hosting Web sites, and that's all they do. They're not running news or mail, or anything like that." But they're still shared. There are still ten or twenty customers on it. So it's not dedicated just to you — it's a dedicated Web server with ten or twenty customers on it.

The other thing about shared servers is that the CGI programming is where you run into restrictions and problems, because a poorly-written program can bring down the server. Let's say this program fills up the disk. All of a sudden that server is no longer going to take connections; it might actually do something stupid like crash the system or go into an infinite loop, and cause performance problems on the server. So because of that, a lot of providers do things like request to review the programs or say you can only use the programs written in their library, written by them, or you can't put CGI programs on there at all.

CGI is the interface that makes your site interactive so people can send you feedback, so people can fill out an order form. Any of the form stuff has a program behind it on the server that processes that form, and that's what we're talking about. So you want to have CGI access, but again, you don't want other people on the system with CGI access doing things that are going to hurt the site. So what do you do about it? You get a dedicated server.

The other thing beyond that which represents a security problem is that usually each customer has an account on the system or some way to upload files, and if one customer's account is broken then the rest of the sites are vulnerable, too. I've seen that happen where one site was compromised, and all of a sudden all the data was deleted — so all 20 sites went down. Just things to consider.

I'm glad they put this in the technical session series. How am I doing here? Is it going okay?

So, [those are] shared server lessons. Ask these people how many customers are going to be on that same server. How many other sites are there? And not just number of customers, but what's the maximum CPU load going to be? Ask whether there are going to be CGI restrictions.

Our company does dedicated servers only. Each customer gets their own dedicated computer, and there are no other customers on it, because the biggest thing is — how do you know that one site might not get really busy and cause performance problems in another site? If it's shared, how do you do resource allocation and do it fairly, so that each get a slice of that computer time? That's pretty tough to do. So if you really want to get extreme, ask for guaranteed server availability.

And ask them what their security mechanism is. How do they prevent security problems if they're giving each customer an account? Or in the upload process, what's the security mechanism for — let's say one customer is uploading their data and they actually overwrite your data accidentally? How do they prevent that? Most of the sites that are out there doing hosting are shared servers, because it's very easy for them to put up one computer and just start tossing customers on it. [Inaudible] four or eight gigabytes of disk, and then most sites aren't that big.

How many people are hosting a site, and they're sitting on a shared server or know if they are? How many don't know?

That's all I have about shared service.

If you have a dedicated server you get around a lot of those issues. There's usually no CGI restrictions because you're the only one putting programs on there — it's your machine to play with. Usually you'll get an account on the system, or even more than one. A lot of times on a shared server you don't actually have an account on it, they give you a space that you can upload files to. Or maybe [inaudible]. I'll talk about that in the upload process.

The thing about a dedicated server is then you can do other things on the system aside from it just being your Web site. It could be your mail host or it could act to hold user accounts for you. We've had customers that have put a couple hundred user accounts on there, and that's where all their user mailboxes live is out on that server; and they run it as a POP server so that all the mail comes into there, and people dial up, people connect into the Internet, and then pull their mail off of it — their own association members or whatever. So that's something you couldn't do on a shared Web server, because it's not designed for that.

We even have some customers that get root access to the system, which you would never get on a shared server. Root access in the UNIX world means you have complete system privileges and can do whatever you want with that system. And that's nice for customers that really want to administer the system themselves, and put some fancy new Web server on it, or some database engine or whatever, that the Web hosting site doesn't support yet. So if you're on the leading edge you might want to get root access.

Here's the one most people know about, and that's the URL appearance. Your URL should be `www.yourdomain.com`. And I'd say insist on that.

How many have heard of PETA, the People for the Ethical Treatment of Animals? Yeah, they're on a site that's doing environmental organizations, I think it's in [inaudible] or something like that. So their URL isn't `peta.org`, which you would expect it to be, it's [inaudible] `org/peta`. So somebody out there registered `peta.org` and they have a Web site up, and I think it's "People Eating Tasty Animals." Check it out, it's funnier than anything. They have meat packing companies, they have fur companies, they have leather stuff. That actually is somebody where I work.

So anyway, get your own domain, your own identity. You're going to want it a couple of years from now so you might as well get it now. I don't care what anybody tells you — get it now, because you don't want that to happen.

So with a lot of places that are doing shared servers, though, you can do a trick with the shared server. You have each domain for the different customers; they each have their own domain, but it's pointing at the same machine. But what happens is that you're pointing at the same Web pages, and so you start off with a single Home Page. How do you give each company their own Home Page without specifying a slash and a path name? They do some trick by giving the computer itself different IP addresses, and then each domain name gets their own IP address, and they're doing something that's called "Virtual Hosting." That is the term that's being used nowadays. But some providers aren't that clever, so they do `www.yourdomain.com` and you get your own domain, but you have to put additional information — `/your company`, or something like that, to get down to your specific Web pages rather than a single common Web page that all the domains are going to point at.

So don't go with that because those people just don't know what they're doing. Your customers will go to `www.yourdomain.com` and not put the extra information, and they'll usually get to the Home Page for the Web hosting service, which should at least have a link listing the customers on this system. But you don't want to have to deal with that.

So go with the Virtual Hosting, or go with the dedicated server where your domain is the only one on that system. And what's the worst in that is when it's not your own domain name but the provider's domain name and then an extension/your company to get down to your files, because then you don't even have your own domain.

If you get really cheap, at a lot of places you can get an account, a regular dial-in account, and you may have space on a Web server as part of that. And so a lot of people have their personal Web pages up — and I don't know if you can see it on the bottom there — it's tilde and the user name, and that will actually look in the user's directory, their home directory, for the files. So that's even worse, because a lot of people out there just don't have clue as to what

a tilde is, and so they screw up when they're trying to type in the URL. So you don't really want to have to deal with that. The best ones are at the top, where all it is, is www.yourcompany.com.

I mentioned CGI access earlier. I think I went over this completely, but basically, every time you run into a Web form where you fill out something and submit it back to the server, there's a program on the server associated with that. And every one of those programs is pretty much different because they're all custom. And so you want to make sure you have the ability to write those programs with no restrictions.

And a lot of times you'll also want the program in environments that allow you to write those programs in whatever language you want, whether that's C, C++, Tickle, Pearl, Java — a lot of people are going to start writing in that. So the term you'll see is CGI BIN access, because that's the directory that they put the binaries into.

I think the other important thing people want is the logs. You definitely want to see logs of the traffic to your site. And the servers keep this information, so the provider should give you your report, whether it's generated once a month or once a week; actually, you should be able to ask them to give it to you every other Thursday or whatever. And then there are programs to process those logs, and usually the provider will run the program on a monthly basis and send you the report. You might also want direct access to those logs so you can pull that off to your own backup tape, or your own disk, and go through it line by line if you want to, rather than just looking at the summarized report.

Not only that, the servers nowadays — it used to be there was just an access log that recorded every hit; it doesn't record user names, it records what computer on the Internet connected to your system and asked for this page, and at what time and date. You don't know what user connected, so anybody that tells you they're doing demographics of your site — they're guessing. All they know is somebody came from AOL and hit your site. They don't know which user at AOL.

Anyway, you want those logs. But better than that now, the servers nowadays will tell you what page that the user was on when they clicked over to your site, and that's the "referrer" log, because that's the page that referred over to your site. So that's nice to have because then you can find out what links on the Web are pointing over to your place.

M: [inaudible]

Joe Peck: You get the URL of the page they were on.

M: [inaudible]

Joe Peck: Yeah, so that means *Lycos* has it pointed over to your page, so that you would know that yes, somebody went to *Lycos* and searched for me and found me there.

M: [inaudible]

Joe Peck: No, you wouldn't know who it is. You'd have in the other log, your access log, you'd have that they were on this computer, and they clicked over to this page at this time. So you know that they were at some machine at *imb.com* and clicked over to this page. So they are two different logs; one telling what page they were on when they clicked over to your site and one telling what computer they were on when accessing your site, and not just the site but which page.

There's also an error log, which is useful. How many of you know there's an error log on your Web server? And you should look at that, because what that tells you is somebody's trying to get to this page, or this URL, and they're having problems getting to it. Those problems might be that they typed it in wrong, or that the page no longer exists, or it might be that the server is too busy. So that's a good indication you might want to go look for another place to host your site.

[Having the] connection timed out — well, actually, don't be too hard on the providers because "connection timed out" would happen when the user decided to go elsewhere and clicked on the stop button. But that may be an indication that it's taking too long, so take it for what it's worth.

Now, I want to go back into the operation side of it. You definitely want 24/7 operations, 365 days a year, Christmas Eve included. You want people monitoring your server to make sure it's always up, and better than that they shouldn't just be pinging the server to make sure it's reachable on the Internet as a computer, they should be trying to pull off a Web page to make sure the Web server on that computer is working. And so every five minutes we're pulling a Web page off each server to make sure they're still reachable. If some system is not reachable, some Web server is not responding, it generates a trouble ticket automatically and somebody's pager goes off, or he gets e-mail, so there's rapid response. So you want that kind of monitoring of your Web site.

The host should have on-site spare hardware; if a disk fails or a CPU dies they should be able to swap it out if you're paying for that. You should be able to get tape backups on a daily basis. They should be doing backups, and if the disk crashes they should be able to swap it out and restore the system from tape within an hour or two. We've actually had a customer — we just brought up their site, the contract was signed saying, "We'll sign contingent on seeing this restore process take place." So we simulated a crash. They asked for it. It's competitive, right? So there should be power backup, too.

Here's another fun story for you, I've got to tell this one. I was working in Palo Alto. I was working for Digital Equipment running the Internet gateway for that company for a while. And behind the building there — Palo Alto is a nice downtown area. I don't know how many of you have been there, but it's a great place. There are nice restaurants in the area, and in one of the restaurants the deep fryer, the grease bucket, the guy was dumping it out in the alley down the drain hole, only it wasn't a drain hole it was a cover over the — well, all the power lines are sunken underneath the ground, and so there's a power transformer down under there. I swear to God. The thing pretty much filled up with grease over time, and started smoking and smelling, and downtown was down for about three or four hours as they cleaned this transformer bin out. And there were some Web providers in that downtown area that were out, because they didn't have power backup. I actually helped them get up. There was a T-1 circuit and no UPS, no power supply backup. So some restaurant employee took down somebody's site. It's a great story.

You might even want to ask them what's going to be the mean time to repair if a site goes down. What's the response going to be? Is it going to be next day, is it going to be next week? I actually tried to start a Web company and I didn't have 24-hour support, so I didn't take any customers because I knew I was going to Aruba for the week. Actually it was Honduras.

[You need] security, not just for the system itself but also for the upload process. We let people use things like [inaudible] if they want to, so it's a very secure log-in for the upload process. There's nothing to say that you're logging in from anywhere; usually what happens is that you develop your content locally, at your place or at your advertiser, your Web developer or whatever, and then you log in over the Internet to the Web site and do an upload, whether

it's FTP or whether it's Telnet or whatever. If that's in clear text, somebody could be snooping those passwords and they could do an upload process, too. We'll see this; actually we've seen it already, but not at our place.

So how secure is that upload process? They possibly might offer the little hand-held cards that generate one-time passwords, so that even if somebody snoops your password it's only good for one session. Or they might use [inaudible], which is a very secure remote log-in type of thing. So that's important.

I think I'm almost done. The stuff on the server — this is actually what a lot of people are clued in about, or they've heard the buzzwords. So, yes, this is a Web server, but what can it do? Can it do secure transactions with SSL or Secure HTTP, where the MasterCard number is encrypted as it's sent up to the server?

So a lot of people want a secure server. People call up and they say, "Well, is the server secure?" Do you mean does it support these security protocols for transacting with a browser, or do you mean can somebody break into it? There are two standards right now for doing the encryption between the browser, the person running Netscape or Mosaic or whatever; and when they type in the MasterCard number on the form and they say, "Submit," it gets encrypted as it's sent up to the server. And there are two standards for that: Secure Socket Layer, which Netscape developed on their own and dumped on the world; and then Secure HTTP, which went through the Internet standards process. I'm biased, I'll admit.

So anyway, the servers — if you have a site that you want to do transaction processing on or take orders on, it needs to support both because not all the browsers out there are Netscape, and I think it'll be fewer and fewer.

The secure browser in Windows 95 supports Secure HTTP, not SSL, so it doesn't matter. As the Web hosting site you need to support all the standards.

You might want a search engine on your server so you can do the search on the site for this string, or this phrase. And so that might be something like WAIS, Wide Area Index Search, or it might be commercial software from Performance Library System, or Verity, or Open Text or — there's lots of them.

You might want a database that you're going to integrate so people can track their FedEx package. That's the best example. But then your hosting site has to have a database engine on it, and usually that means an SQL, Systems Quarterly Language database engine, like Oracle. So, yes, you can rent space on the server, but is it going to offer all the things you want?

Other stuff on the server might be if people want a conferencing-type system, a bulletin board-type system where other people can post things on the page like restaurant reviews or user comments. And there is software out there that is public domain called *Hypernews*. It turns out that other commercial companies are starting to make their own little nice interface to it, and stuff like that. So is there a conferencing system-type of stuff that's available on the server?

Problem for the providers is, well, everybody wants everything, and it makes it interesting keeping up. So it's nice because I get to keep track of all the nice developments going on in the Web space.

Speaking of Web space — is there VRML on the system, etc.?

The last thing, I think, is the upload process. And the main thing is that people want to it to be easy for when you develop your content. "I don't know UNIX, but I want to transfer the files up. How easy is it?" It depends. There's actually some server software out now that's pretty nice; you develop your content and you click on "Save," and it will copy it up to the server. I haven't checked out how secure that is yet, as to what they're doing. But in most cases you're just using the file transfer protocol to transfer the files over. You have an account on the system, you log into it and transfer the files up. But then you need to log onto the system using

Telnet, a remote log-in, and change your permissions on those files so that they're world-readable so that people can access it. So it's usually a two-step process to do that.

For a lot of people, though, they don't deal with a lot of this. What they do is they hire a Web development company that may be working with the Web hosting service, or it may be that they're doing both, and the user just says they want these pages and the Web developer handles all of it. So I think that's the typical case, because most people don't want to have to deal with this level of detail. So your Web developer needs to be working closely with the Web hosting service, if they're not the same. My take on it — of course I'm biased — is to go with the Web hosting site that has the best infrastructure and is capable of handling the site well, but that same company should be working very closely with the Web development firms. I'd say that's the best combination; but that's just because that's what I do.

Server performance — I mentioned bandwidth overloading. Now there's server overloading where things that are important on the server are basically how fast the server can pull files off the disk and pass it out over the network. And so that boils down to throughput, like buss speeds, I/O bandwidth and CPU speed, and how much RAM there is in the system. If you really want to get technical (I see people leaving), but all computers are not the same. We actually use some old Sun systems that have about 20 times the performance of a nice 486/66 — twenty times the data throughput based on CPU speed and I/O bandwidth, and yet they cost us about \$85 because Sun doesn't even make them any more.

Actually, the thing that people actually ask us a lot is, how many simultaneous hits can this server take? How many of you have measured it that way? Yeah. "I'm going to get a million hits a day; can your server handle it?" What's the distribution over the day? Is it in a one-hour period? So that's determined not just by the CPU and server hardware, but also the server software. You'll see a lot of people on the show floor talking about how they have multi-threaded servers, meaning they can handle more than one process at a time. So my only comment on that — well, two comments: make sure your server is not under-configured for the amount of hits you expect to take; and hey, go UNIX because it's designed for handling multiple connections, and usually the hardware that's designed for a UNIX box has the I/O bandwidth built into it.

I feel like I've been doing this for too long, and I'm not talking to UNIX people any more.

Anyway, the server software is steadily evolving, getting better, and the big thing there is the multi-threading. The thing is, you can get public domain software servers that are free, that run equally as well as the two or three thousand dollar commercial software. So they're adding things like the logging capabilities and the software to help you thumb through the logs easily.

Oh, the last thing, and this is fun — I think it's last because we're running out of time, right? Yeah. Contract issues; when you sign a contract, a couple things to look at are what happens if you want to move your site, how easy is it going to be, what are they going to try to stick you with? So termination process — I saw one provider (this is really, really bad), this one company said, "Well, we're tired of you because you're not providing the support you promised, so we're going to move." This provider changed the passwords for this customer's account so the customer couldn't pull their files off. I don't know what happened with that one.

The other thing to look into is what happens when you need to transfer the domain name. That's a process you'll have to go through, because usually this provider has registered your domain for you and is running the name service for you. You're going to need to move that over to your new provider. But the key thing about getting your own domain name, and using your own domain name, is that it's going to be transparent when you move it. If your domain is www.provider.com/your company and you move to another provider, none of your URLs work any more. None of the places that link to your old URL are going to work because they're still pointing to that provider.com site, and not your own domain. And so all the places

that you've worked so hard to get references in the Web over to your site are no longer any good. So that's why you want your own domain.

So the other thing on the contract is to make sure they put in the contract how easy it is to upgrade, what the costs are and so on.

The other thing on this is the CGI programs. Usually, with the Web developers, you're paying them to develop the programs to search through your real estate database or whatever, so you're paying them to develop these programs to process the information and give the right responses to the customers. And when it comes time to terminate, well, did they develop that for you, or develop that for themselves? Do they own that CGI program, or do you?

For example, this one Web development company was doing software specifically for real estate industry Web sites, specifically for the real estate industry, and so they would search through the database and find, you know, houses based on location and cost range, and type of house and all that. So all these programs were written and the database was written to search through it, and they were doing it because they intended to have several real estate agencies as customers.

I think, though, that the first one paid for most of that development work. So you might want to look at, "Well, if I'm paying for them to develop it, can they sell it then to my competitors? And do I own the program if I move somewhere else? Are those my programs?" So that's something to think about that most people aren't looking at yet. And for most Web developers it's not in the contract, so they're doing it for themselves in a lot of cases.

That's it, yes. A couple pointers — there is the Web FAQ, Frequently Asked Questions. One question that a lot of people ask is, "Well, how can I find an index that places at hosts sites?" If you go to the Web FAQ, there's an entry in there that says, "Can I lease space on a server?" I looked six months ago maybe, and there were 70 companies or so; there's probably 100 or 300 now. So anyway, that's in the FAQ.

INTERNET TECHNICAL ISDN: EQUIPMENT AND INTEROPERABILITY

SPEAKER

Richard Brennan

Technology Manager, AT&T Network Systems

Richard Brennan: Some people still try and call us Western Electric, but that's not going to be our new name. I think the most popular vote is "Undistinguished Symbol, the Company Formerly Known as Western Electric," and so about March when we do an IPO stock offering for this little start-up \$20 billion company we'll have a new name; but meanwhile, my role is to provide ISDN to people who are service providers. The company that I work with directly, because of the area I live in, is Pacific Bell, so some of the examples I'm going to give you are from the other coast — and that's not just because I'm from there, it's because ISDN seems to have done not only very well on the Pacific rim, California included, but it's especially well-tariffed, well available, and well-supported in California. One of the unfortunate things I'm going to tell you is that it may not be true everywhere. California certainly is a state that we would like to get the entire nation to [emulate].

What we're talking about today, in this session — and this is the first of three sessions, and so the sum of the three sessions will constitute essentially an ISDN tutorial — the one we're gonna talk about right now is "ISDN Equipment and Interoperability." So I'm going to do a little bit of an ISDN overview to make sure we're all on the same page, and then we're gonna talk about some of the considerations you might want to consider as you go and decide on an equipment purchase of ISDN equipment to support either your personal use, your organization's use, or — if you're at the other end — setting up a hub or a dial-in site over the public network.

And that is, I think, the unique thing about ISDN — it is the standard for the future. It's the public network, digital-access pathway that's here now. It's here internationally, and it'll be here when everybody's trying to decide whether cable modems are neat and what protocol that ought to be, and whether interactive television is going to deliver the Internet and what protocol that ought to be. And all those things will happen. ISDN is here now, and it is something that's reachable to many locations on the same pair of wires that you have in your home and in your business today.

One of the other major things is that you can't equate ISDN digital technology to the older analog technologies. It was very popular a couple of years back to say "Well, ISDN is going to be exactly 1.7 times as good as an analog line." Well, the answer is it may be just as good, but it [also] may be four times as good, it may be ten times as good, depending on what you're doing with it. If you can't get it to your home or to your business when you want it and where you want it, then it may not be very good at all.

So we're in the midst of all those situations, but I think it is a positive thing that it's becoming more available and more supported by more service providers. You see out on the floor here a large number of ISDN dial-in devices. *MacUser*, this last month, said "Hey, it's what you have to have to get to the Internet." Those are the kind of industry things that are turning this around and making ISDN very viable.

What is it? It is, fundamentally, one of the last things in your home to go digital, and one of the last things in your office. We've had telephone systems around since day one, and that's probably the oldest electronic device any of us were familiar with, the rotary-dial telephone. And it's amazing that the technology for analog telephone lines has lasted as long as it has; you could take one of today's fast modems and plug it in to your grandmother's phone line, and

subject to a few considerations and some noise on that line you could probably make it work. In terms of the analog technology, I don't know of any other technology that basically lasted in its current status for well on to a hundred years... Well, it's time to change that, and the change involves going to pure digital like all these other technologies have gone. So, out with the analog and in with digital; and the fact is we now can get that to you on an individual telephone line basis. The digital means that we are no longer trying to stuff the zeroes and ones out of your computer, out of your TCP/IP application, and down a nice noisy analog line.

We're not converting it to tones, which is all a modem does, and trying to stuff that complex series of tones down an analog line; we are running both voice and data in a single bit stream down a digitally-encoded line which allows for ISDN digital devices, and I do not call them "digital" modems because they have nothing to do with modulation and de-modulation. ISDN digital terminal adapters now can easily run ten times as fast as the normal on-the-street modem technologies, and I think that's the big advantage.

I don't know how many people have raised their hands and said, "No, no. I want the slower technology. I'm having trouble reading that screen as it scrolls past me, so please slow it down." We just don't see that; everybody wants more processing power, more communications speed, and I don't see ISDN being an end [so much as] a point on a path towards broadband communications technology. So we can mix voice and data in one device. We no longer have to have two lines, for instance, to do a voice conversation and a session up to the Internet; we can do that all on one telephone line. At my house that makes the wife and kids happy because the girls want to talk on the telephone to other people. They don't want to be logged on to the Internet all the time, although they do get access from home.

What do we need to support ISDN? Well, you need a telephone company service provider who is willing to sell it to you. That could be either in a business or in a home, but basically the same pair of wires that they put under the street is going to serve ISDN. Subject to some restraints, it's a higher speed digital signal that likes to run over nice, clean copper wires, but it's gonna come in through the wall, through a wall jack just like you have now.

And now we start getting the stack of boxes, some of which we'll talk about — how those stacks of boxes are gonna shrink down and become one box. And you'll see a lot of that out on the trade show floor.

There are three functions here that we need to talk about. ISDN lines need power; they are not powered from the network like your analog telephone is. So, when there's an earthquake in California — or on this coast, I guess, a hurricane — and the power goes out, you are not going to be dialing to the Internet unless you've got a big battery on your laptop, and I question how your PC is running anyhow. That's not what you'd really want to rely on. I would always recommend having an analog line somewhere to use during emergencies, because that line is powered from the telephone central office and will stay up.

You then need a little device called a "network termination," and what that does is take the two-wire interface from the telephone service provider and convert it to a four-wire balance termination.

You then need functionality with a terminal adapter. Terminal adapters replace the functionality of modems in an analog environment, so you no longer use a modem in most cases when you're trying to do digital access through this new network.

In a little more technical diagram, here are the actual reference points in the protocol — and remember, this is internationally standardized. This is not something that was invented, you know, on Route 128. It wasn't something invented in California. It's not something just being supported in those locations; this is an international standard and, in fact, it is being mandated in Europe and in the Pacific Rim for inclusion in public networks.

I'm going to take questions at the end here because I want to get through all the material. I'm going to try and do this real quick, in about half an hour, and then take about 15 minutes of questions at the end.

So we have the local exchange, which is the telephone company switch, the network termination and the terminal adapter. The terminal adapter is used to get back to what we call an R-interface. R-interface is the ISDN's way of describing the older, pre-existing data interfaces [like the] RS-232. All of those interfaces which are not brought under the ISDN umbrella are called R-interfaces.

ISDN lines come in two varieties. There's the U-interface — remember U for universal service — and that's a two-way ISDN line. The NT-1 converts it to the T-interface — remember T for two-pair, and that's not what they stand for, that's just how I remember them — and that's a four-wire interface. And that's what most stand-alone ISDN devices run on today. The T-interface is internationally standardized, and the U-interface is standardized for use here in the United States by the ANSI committee — the ANSI standard U-interface.

What can I run over an ISDN line? Well, the line that's going to be delivered to you as an individual user is called the “basic rate interface.” It's the new digital telephone line; it essentially has user-bandwidth of about 144,000 bits per second, so you can see why I'm getting that number of around ten times the capacity of current in-the-market modems and perhaps five times as fast as the V-fast modem — and remember, it's pure digital, so you don't get that “fax machine effect” where you hit a dirty line and the speed goes down.

This is end-to-end digital, so if you have a connection it's a good connection and you're running those kind of communication protocols. You can then get voice and single-channel data, which I'll here call “point-to-point protocol for Internet applications.” [You can also get] multi-channel data — and we'll talk about multi-length protocol in a few minutes — packet connections, X.25 packet switching is built into ISDN, and also something called “signaling.” You don't access signaling directly, but it's the way you talk to the network and the way the network talks back to you. It says, “I want to call this number in France on voice on one of my channels up there, and at the same time I'm hooking up to my Internet service provider on data on the other channel.” That's how you command the network to do that for you.

Where might you dial to? You could either dial to another basic rate interface or you can dial to a primary rate interface. Primary rate is a T-1, one-and-a-half megabit-type connection. It's not as intelligent as the basic rate interface, but it has more capacity, so that's what Internet service providers, corporate Internet gateways, and educational data centers will use to allow people to dial in and access ISDN services through the network. And once again, it's controlled by a signaling channel, so each one of those channels can be a different kind of a service. They can be a modem service, a digital service, or a packet service on a channel-by-channel basis.

By the way, for those of you who are trying to write all this down on notes, you'll notice that I don't have a lot of bullet items; I prefer the graphics style, and the slides will be both on the CD-ROM, which is available through the conference, and also be up at my Home Page, which is www.image2000.com.

So here's the typical model of an individual user dialing in through an ISDN adapter into a digital network and coming out to some kind of an Internet service provider, and that's usually a kind of a gateway at the service provider serving tens or hundreds of users simultaneously dialed through the network. I'm going to view some of the configurations, and this is important because it gets into what kind of equipment you might want to buy. If you'll look up there, I've characterized these; the first unit here is an ISDN digital telephone set. This is a voice-user who wants to casually access the Internet. They might use the data port in the back of that telephone set to access the Internet, and so they're not really focused on the data

application, they're focused on the very powerful voice interface you can get on ISDN. This is more of an example of an office worker who perhaps wants to move an entire office home and have a very rich voice functionality and also be able to communicate to the Internet or with the office.

The second one is data plus casual voice. Here I've got a PC board in the computer. The PC board is able to offer a richer set of data services, but because it only supports an analog telephone it doesn't have all the button features that you'd want for voice. You've got to decide which it is I'm trying to do here, [either] mostly voice or mostly data. You don't actually have to make those decisions quite as harshly as I've portrayed them here because you can blend some of this together, and we'll talk about that in the next slide. You can put a voice station and a COM port connection through a data voice terminal adapter, or you can go straight with a 10BaseT-type connection out of a NIC board in your computer — or out of the AUI on a Mac — and come right in to a 10BaseT connection in the data adapter. Most of the 10BaseT adapters are supporting two channels of PPP data; that's that multi-link or MP protocol, and that's very important in interoperability between these units.

Now, one of the nice things about ISDN is that the whole linear relationship of a phone line is a phone number connected to a thing called to a phone. That's all gone away; we now have a set of software relationships which means a pair of wires may talk to many devices simultaneously and also may have many telephone numbers and many data services running simultaneously. Actually, at the bottom, the protocol can support up to eight independent devices on ISDN basic rate lines simultaneously. Remember, there are only those three channels, two B channels and a D channel, and you're all bidding for that channel capacity so you may not all be able to work at once. But if, for instance, you wanted to put a video conferencing unit and an Internet access device or LAN access device and a voice phone on the same line, that's very achievable — you just can't use them all to their full capacity all at the same time. Some things you need to be careful about, though, are if you buy a U-interface box and there are a lot of those on the market, if it takes the U-interface directly into the box and does not give you back the T-interface you are locked in to that one device on the line. You cannot add the second through eight devices on the line.

The U-interface does not support the multi-point capability; only the T-interface supports that. So what you have are a number of other options which... There are devices which support both the U and the T-interface. Some devices support a telephone set directly, like an RJ-11 jack out of the back of the terminal adapter. There's a number of variations here. So if you get the unit that has the NT-1 functionality built in, look at the back of the box and see if it gives you back the T-interface out of that NT-1, and that will tell you whether you can add additional devices to the line. Look at the other side and see if it has an RJ-11 voice jack built in. Some have none, some have one, and some have two RJ-11s.

That says that it has a codeck functionality there to convert your analog input, which could be either a telephone or a fax or modem into the digital format running on the line. You cannot run a modem signal directly into an ISDN line without using a terminal adapter — with one exception, which is sort of a spoofing of the protocol, and I'll talk about that in a minute. One of the important things for you to consider is what you are going to be hooked up behind, and so you need to know a little bit about where you're gonna be and what kind of services from the telephone network are available to you.

At a corporate location you may either have connections to an inter-exchange carrier or a local carrier's connections on either BRI, Basic Rate or Primary Rate services. At home or in a small office it's almost always going to be basic rate services, and like all good standards they're great because there are so many variations of them that you can adhere to, so I've just listed [them]. You'll see the terminology "NI" for National ISDN. National ISDN is basically the

Bellcore, which is the agency that is the technology and research group of the seven Bell operating companies working with the industry to define a common set of ISDN signaling commands to let equipment work across all hardware, software, switch and end-point combinations. Before National ISDN was invented in about 1989 there were implementations called pre-national, pre-NI or custom implementations. You need to be aware of what kind of service is available to you and whether the equipment you're buying supports that particular flavor of service. Currently, most equipment has selections for the AT&T [inaudible] the access switch, the NORTEL DMS switch and National ISDN-1. That's the most common combination right now; however, when you're buying equipment you need to look at that list and talk to the service provider in your area or talk to your corporate or your educational network provider and say, "Hey, what kind of service am I going to be putting this behind and what are they going to change it to next year? Are they going to bring it up to NI-2 standards?" That might be important in the next 12 to 18 months.

Once again, just like the selection of hardware, these standards [inaudible] because there are so many ways that you can do a TCP/IP session. They're ranked sort of in order of desirability here, with the first ones being the least desirable. TCP/IP was originally run down some really slow X.25 networks and so it's built for that kind of a reliable network connection; and since the ISDN supports X.25 up to about a 19.2 speed through the network, you can actually get a 64 kilobit packet connection to an end-point. You can run it on X.25. I've done it in our laboratory. It was nice; I made it work and then I threw that away and started working on these other higher-speed connections, because it's not what you really want to do. V.120 is an asynchronous protocol. V.120 asynchronous is the same to ISDN as V.34, V.32 is to the modem world. It is the international standard for asynchronous connectivity on a digital line.

PPP protocol originally was invented for a single protocol stream running between the user and the network. What we get into is that ISDN is built up of many channels, so there are several ways of handling multiple channel calls. They're called "bonding PPP" and "multi-length PPP," or the MP protocol, and the difference is that in bonding the hardware or the application doesn't know about the multiple channels; it sends out one stream, and bonding takes care of breaking up the channels and reassembling them at the other end.

In the multi-length PPP, the communication protocol does understand the multiple channels and so it's aware of channel constraints, and it does the application of breaking up the communication and sending packets down different channels. Here is a little diagram explaining rate adoption. The V.120 standard — remember, your serial port on your computer is running at 38.4 or 19.2 and the channels in the public telephone network are at 56 and 64 kilobits, so that does not match up well and we have to "bit-stuff" all of those COM port speeds up to the 56 or 64 kilobit level to get them to run to the network. There are four different standards for that, three of which are obsolete' they're AT&T, DMI on NORTEL's T-link and the older, international V.110 protocol. The standard that everybody seems to be building in their product now is the V.120 standard. Remember, this applies to async only, but some of the devices you'll see do some async-to-sync conversion in the device, and so you can actually run serial port connections into a terminal adapter.

Here's a diagram showing the difference between the bonding and the multi-link protocol. You can see that in the bonding, the IMUX, the inverse multiplexing capability, is essentially external to the application; whether it's bundled in the same box is irrelevant. It performs a function that your application is not aware of, so your application sends out a single PPP protocol to access the Internet, and this IMUX, as we say, slices and dices the packets up and spreads them over multiple channels and then another matching device at the other end reassembles that.

Bonding is a multi-vendor standard for doing that protocol, and many of the devices you'll see support bonding. Multi-length PPP is perhaps the key interoperability element in ISDN-Internet testing. Under the auspices of the California ISDN user-group there has been a number of interoperability shops done in California, and I'm going to show you the results of that a little bit later. The key thing is to allow multiple vendors, both at the single end-user side, the small LAN hub side, and at the ISDN gateway side to be able to interoperate effectively using this protocol so you can play mix-and-match.

So, a key question to ask — depending on how you're setting this up and whether if you're dealing with an information service provider or Internet service provider — you need to ask them what flavors of equipment they have, and if they handle bonding and if they handle multi-length protocol MP. If they say they're handling that, which equipment types are compatible with the equipment they're using in their gateway? If you're setting up your own network, you need to look at some of the test results. [Bob Lerbo] has written that up for a number of the magazines, and those reprints are available at several of the vendor's booths because they say favorable things about several of the products that are on show here today, including Gandalf, which I know has it, and Ascend also has it in their booth.

So those are a number of the testing things that we need to do to make sure that we can communicate. A bonded call will not talk to an MP protocol call, so you can't hairpin those two communication protocols; they have to be symmetrical and the same, both ends bonded or both ends multi-length protocol.

[Next is] equipment examples. This is just a short list of 30 vendors that we did some testing with, and there really is an authoritative place to go. As soon as I get off the mic here I'm going to go up to Dan Kegel's Home Page at Cal Tech, which is the authoritative ISDN page. Basically, everybody starts there and then starts looking for information. The quickest way to find the URL for it is to go up to *WebCrawler* and put in "Kegel" and "ISDN" on the same line; then just do a *WebCrawler* search and it'll come out as the top item on the *WebCrawler* search.

3Com has taken over the old access work products and added the multi-length protocol to that. Ascend is a pioneer in ISDN terminal adapters and has been there since their work with Haysoft Combac many, many years ago. Cisco has just acquired the CombiNet product, so if you see me not referring to CombiNet's... I think they've snuck into a few of the slides here. Cisco's now acquired the CombiNet product and renamed some of those *CiscoPro*. Farallon has just come out with a new ISDN access device, and I've worked with Farallon on-and-off in vendor relations as they've been developing ISDN gear. Gandalf has some equipment that's just passed that multi-link testing. The IBM *Waverunner* is a good application, and the IBM *Waverunner* uses a DSP instead of the modem "twinsert," a modem-like signal into the voice-bearer capability of ISDN. Modems to the network are voice calls, so a digital call that you may originate over a modem is not the same as a digital-bearer capability through an ISDN network — they cannot talk. The only way you can do that is to actually have a modem chip talking to a codeck chip, which digitizes the signal to do what the *Waverunner* does, which is take a DSP and emulate that process.

The DSP acts as the sum of a modem chip plus a codeck chip and inserts a digital signal that was originated right on the board. KNX is an English vendor with some networking. Motorola *Bit Surfer* is probably the price leader in ISDN connectivity. You can go down to Fry's Electronics in Silicon Valley and buy a Motorola *Bit Surfer* for \$249, and we heard they were gonna have a good price at Christmas time that's lower than that. It raises the question, "If an ISDN device is only \$249.00, given its constraint in this functionality, why would you pay \$350 for a modem?"

The answer is probably because the ISDN service is more expensive and not as universal; but technologically there is no reason why most ISDN devices should cost more than comparable functionality built around modem technology. The industry has just waited for the dynamics of the industry to cause enough demand to make single-chip ISDN solutions, and that's coming to fruition now. We're having single-chip ISDN network interface, a single-chip ISDN processing core, and I think you'll see the numbers basically come down so that an ISDN terminal costs the same as a modem — the same functionality but with five times the speed.

I think that's where we're going to get to in the next eighteen months. So here's the full URL for Dan Kegel if you want to [go to] it directly; then if you also want to look at telephone service providers, you need to start perhaps at bellcore.com or throw in nynex.com or pacbell.com, any of those. Most of those will have a service description of their ISDN services up on the Net, and then you can call and ask about what kind of services are available.

I caution you, many people in many areas make the same mistake of calling up their residential service adviser from their phone company and saying, "Can I get an ISDN line in my home?" And the answer usually comes back, "How do you spell ISDN?" And the problem is that the residential folks in many of the telephone companies are not trained to handle inquiries on ISDN. Pacific Bell, who sold me a residential ISDN line, handles that by a special phone number and a special group that bypasses their normal residential customer service, so they're not geared up yet for those hundreds of account reps to answer things like, "What's the size on your X.25 packet session?" You know, they don't want to deal with that, so they set up a special number.

At Pacific Bell it's 1-800-4-PBISDN, and you call a number like that and they know what you're talking about. They know the equipment and they know where you can get it. They know whether you're behind a DMS or other phone companies that might be behind the [inaudible] switch. They know whether you're national ISDN-I or whether you're a [inaudible] custom, and they can take your order and, in fact, advise you as to what things will work in what combination.

Your business office, however, may be the people to call. If you call a business office and ask for ISDN, and they say, "Oh, by the way, one end of that is going to be at my home," then they are probably going to be able to handle you.

I think I'm at the end with the slides here. Oh, the interoperability testing — CIUG, with the assistance of Pacific Bell and lots of other people, [inaudible] Consulting have put together this interoperability testing, and we've done this a couple of times now. And what this allows is a natural workshop environment with a mixture of DMS and [inaudible] alliance to allow the vendors to go into a lab — usually they've done this at Pacific Bell's headquarters site — and actually do the plug-and-play testing that you need to assure that you can talk to other units. They've tested over 30 devices. The people who like their results are obviously publicizing their participation in that.

Some other people have had to go back to the drawing board and do a little more work, and so you don't see them mentioning that they've been there. You can get some of the details at ciug.org, which is hosted by IBM's Almaden Labs — or at least the service site is. Stan Kluse from Lawrence Livermore National Labs is the chairman of the CIUG, so you can see it's got some very broad industry support. Xerox PARC is also a heavy ISDN site in California. So with PARC, JPL, Lawrence Labs and IBM labs all working on ISDN as users — pure users, not developers — that's the kind of environment we have in California. I have that same kind of service at my home on a single line; I can tell people now that I have the same service that Xerox PARC has, but I've got it at my home. A lot of them do, too.

Let me shift gears here. One last slide. What you need to know about switch types... The MI status. Whether you're an ANSI U-interface or T-interface, if you're behind a PBX you

may be behind a T-interface, or if you're in certain Centrex situations, you may be behind a T-interface. Once you put an NT-1 on a U-line, then you have a T-interface. The most commonly missed item in provisioning an ISDN line is failure to write down the SPID, the "service profile identifier," that somebody told you. In most cases they forgot to tell you because they don't have a form to write it down on — it's, you know, a little post-it note they glue to the back of your telephone.

Actually, they're probably written on the telephone jacks on the wall; that's where I've seen them the most often. The SPID actually controls what services the digital switch sends to your device, because there could be up to eight on the line. Each device has to be uniquely defined to the network, and so without that SPID, you're nowhere.

Now, you may get the answer that a SPID is not required, especially if you're on a AT&T 5ESS line from any of the local service providers or any of the local phone companies. That probably means that you're on a 5E custom ISDN line which does not require a SPID for a single device. With all DMS implementations, all ANI implementations, you'll need to have a SPID, so pound the table until they give you SPID information and make them tell you which directory numbers have which SPIDs and what set of services goes with that SPID. If I had eight devices on the line, each device would have a separate SPID. Some devices can have more than one SPID, so there is no nice, linear relationship here. Everything's under software control, and you need to be informed as to what those services are.

Now we're going to go back and look at a few of these pages. This is where you'll be able to get copies of the presentation: This is our site at image2000.com, and I'll go up here and go to Dan Kegel's page. This is the opening of it, and basically what Dan has here is a set of announcements and lists of equipment. I think he's conservative here; like I said, if they break the \$300 price, Fry's already has them for \$249 and we hear the bits are [going] on special towards Christmas, so you know that starts to become very attractive. If you go into the terminal adapter list here, you'll see long, long lists of corporations — 3Com, Gandalf, IBM, and here's the Motorola. You can see that low price at the bottom there. US Robotics... I thought they made modems, but suddenly [they're into] ISDN. What's that? They're out there. They are all out there.

There's a number of other elements here; as you can go down, you can look under service providers and you can look by type of adapter. Unfortunately, for those of us on the Macintosh, there aren't that many choices of the Euronis — well, they used to be called Euronis. *The Planet Board* is about the only new bus ISDN adapter, unless you're one of the lucky few who got one of Apple's original Apple-made ISDN bulletin boards that, you know, [kind of just] went away. But those are now archival quality.

So most of us use external adapters, and what you'll find is that those work with anything... Motorola, to my knowledge, didn't have a booth here, but most of these other vendors are represented on the floor and I encourage you to go and sample the spec sheets on all those and make a decision.

Just a little war story... I ordered my ISDN line for home at the Internet World [Conference in] San Jose, in May. The following Friday they called me up, and we negotiated SPID information. Two weeks, a week from the following Tuesday, they were out in my front yard cutting a four-foot square hole in the sidewalk to pull the extra pair in. Previously I had three analog lines, but those are assigned to my wife and my two daughters, so I didn't have one; now I have digital so I can now access the Internet from home. That was in California, [and there was a] \$37 installation fee and \$25 a month.

So now I'll accept the tears and jeers of the crowd here. There's a question from right there.

M: [inaudible]

Richard Brennan: Bank teller machines? Oh, I'm sorry, the other ATM. Let's see; ATM to your home today, would be what? \$3,000 a month, a \$1,500 interface adapter, \$29.99 a month and — you know, I'm actually working in the group that's providing the hybrid-fiber coaxial network to Pacific Bell which will deliver those types of services to three million homes in Northern California over the remainder of the decade here. By the year 2000 three million homes will have the capacity to provide that kind of — think of an ATM 25 network in your home, plus video conferencing, plus interactive television — you know, all the stuff you wanted. The capacity and the network is there, but that's a little project valued in the \$5 to \$12 billion range and it's not going to happen in, as you said, three months or six months. There is essentially no way to cost effectively get large volumes of — and I'll stress this — symmetrical ATM service to your home. There will be people who are proposing some one-way technologies that say they'll deliver you high-bandwidth, and that may work well for certain kinds of Internet view-only applications but it certainly doesn't work for a telecommuting application, something where you want to be peer-to-peer.

An emerging trend in data communications is going to be data collaboration. [ATM] will not work as well for that, and it certainly does not work at all for things like video conferencing, so asymmetrical ATM will be achievable perhaps in two or three years. Symmetrical ATM is going to wait three to five years and still be expensive.

M: [inaudible]

Richard Brennan: Yeah, that was a couple million lines of user-interface code behind the BRI because it was intended to point at a user. So what is the call-forward, busy, don't-answer-on-data feature for PRI? Those kind of things don't exist for BR either, but call-hold, call-transfer, drop — all those things are understood by a basic rate interface. PRIs have trouble with some of those concepts; they don't know what feature buttons are in the voice environment, and they may not have the same richness of data control functionality that a BRI has. It's all in the user interface and mostly on voice.

M: [inaudible]

Richard Brennan: Well, I miss it because I think in certain areas you can get it at home now.

M: [inaudible]

Richard Brennan: Oh, mobile? So you're talking about cellular and wireless technologies, right? People are gearing up. Some of the PBX's now might call Northern AT&T [and see what they] can handle, to make sure of BRI and PRI services. Wireless is an interesting one. Everybody says, "Why are you doing this? We'll just go wireless." You either hear of them doing broadband LANs for tens of users or tens of megabits for several users; you don't hear them talking multimedia broadband for hundreds of thousands of wireless users, and that's what you need to do whole communities on broadband wireless.

Broadband wireless is a reality. There will be things like MMDS, which is one-way television service, asymmetrical. You can't talk back very well, so doing multimedia and receiving things like interactive television are two very different applications. In the press release wars they tend to get blended together and talked about as if they are the same thing.

The question I always ask is “Can I talk back?” You can do MPEG, too, in your home. Can I talk back? No. So that’s the question, how much you want to talk back. Otherwise, downstream-type services from satellite, from terrestrial wireless, and from cable modems and things like that are very achievable and will result in some great services at very low costs. More questions? Yes.

M: Do you know of any [vendors] who are providing [inaudible] with the ISDN?

Richard Brennan: Yes, there are several, both at the local side and at the host side. I believe that, yes, Robotics has that. I believe that Gandalf has a model that supports that — and the other vendors are probably going to throw rocks at me because I’ve forgotten who they are, but certainly they do exist. The IBM *Waverunner* does it with a DSP. So there are good examples of products which imbed either the modem or the DSP functionality inside the ISDN device to act as if it was a fax modem or regular modem.

The Cisco *ComNet* boxes and the Ascend boxes support that with an RJ-11 jack in the back of the ISDN internal adapter, and they do it with brute force. They throw a codeck chip at the analog signal right there and digitize that signal for the network. Question?

M: FCC and ISDN?

Richard Brennan: Oh, how many calcs do you want on your ISDN line? No comment. I think that will be decided much in our favor. Frankly, the calc is the charge that was put on the telephone line to pay for things like universal service, and somebody in FCC decided, “Well gee, if the ISDN line can support two B channels, that’s like two telephones, so there should be two calcs.” I think that’s a very linear interpretation of the program.

M: What about the [inaudible]?

Richard Brennan: Good question. They didn’t say eight calcs, they said two. It’s like, “So where do you go?” You know, the questions are, “What should it be? And how many addresses were on there? Were there 128 phone numbers on those two devices, or just one? Where’s the value there?”

So there’s a whole conceptual question that I don’t think was addressed by the FCC, and I think everybody was collectively throwing rocks. You can read the “Comp Decom ISDN Newsgroup” and get a lot of the thread of that conversation. [There’s] also some additional words on the CIUG organizational postings, and also at Bellcore. No more questions?

M: [inaudible]

Richard Brennan: That’s Ascend’s proprietary implementation extension of MP. They have announced that they will make that protocol available to the industry, and hope to get a consortium to lobby for that as being the further extension of the MP protocol, which is RFC-1717.

M: My supervisor at USWest just filed for [inaudible].

Richard Brennan: Remember, I speak for the equipment manufacturing side of AT&T, not the service provider side of AT&T, so separate that right now. ISDN is not cheap to provision to the user, and I think people, now that we are starting to address the “how do we get to the

users” question, then somebody up at the CFO office says, “Now, how do you make money doing this to user?” So there are some people taking a look at the value equation in ISDN. What is it worth to people if it can support five times the speed and eight devices? What’s the value proposition there?

I don’t know that you’d have to just do a knee-jerk reaction to tripling the price, although somehow that doesn’t really seem right. You have to look at the set of services. Is it measured rate? Is it flat rate? How much are they charging you to install it? How much does that bring the per monthly charge to? In Pacific Bell, they said it was \$37 to install, \$25 a month and they waive, I think, the \$150 installation fee if I keep the service for two years. Now, that is about as cheap as anybody has tried to provide the service. Can Pacific Bell keep going down that road? I don’t know how long that will be possible, but certainly that’s the best in class right now for ISDN service. Yes.

M: Do you think the [inaudible] of whether a serial parallel [port].

Richard Brennan: [Inaudible] of serial ports are way beyond their technological life. You know, to call RS-232C a standard is somehow an oxymoron... I currently like the 10BaseT solutions because I think they’re more flexible. I have both a Mac and a Windows machine in my home, and I can hook both up simultaneously; then my daughter can spool her laser printer jobs from the bedroom out to the laser printer in the front room. That’s how my house is wired and so it’s device-independent.

I think as we go to things like ISO Ethernet — which is 96 B channels, plus D channel plus Ethernet — as we go to other protocols, I think that for the distribution around home and business, the next generation of LAN interfaces will continue to predominate; however, if you’re doing a real office with knowledge workers who are on the telephone a lot, if you need that to run a home office, the idea of running one of those devices directly off the phone network and having a robust voice service there and then — perhaps doing separately to get a data service — seems to have a lot of merit. Even in the most “propeller beanie-type labs” you find telephones next to the computers that are in the lab, because anybody who’s having to do maintenance on those computers or remote diagnostics or work with the user at the other end has to talk on the telephone.

So you need telephone access if you’re using a computer for anything that’s in the business world. And I think that’s what’s driving those, too; they will come together so that the phone is part of a computer. The telephone, as a device, is going to go away; the telephone becomes a hardware-software application capability inside your desktop.

I think that will go away from the serial ports. There is a new generation of high-speed serial ports coming out, [inaudible] and Firewire which allow things like that to be done more effectively. But right now, because of costs, I think 10BaseT has sort of been the leader.

I’ll keep going because I’m the next two speakers, so I can use my own time up. By the way, if you do want to stick around, what you’ll suffer through is about a 10-minute review of what we just said here, followed by a discussion of service provider issues, and the third session will be how to do it from home. So I’d like to thank you for your participation, and if you have any questions, I’ll keep taking them here. We’ll just keep going, but meanwhile we can bring up the lights and let people go on.

INTERNET TECHNICAL ISDN: SERVICE PROVIDERS

SPEAKER

Richard Brennan

Technology Manager, AT&T Network Systems

Richard Brennan: This is the session on ISDN access to the Internet, focusing on Internet service providers. What I'm going to do today is take a rather broad interpretation of what an Internet service provider is going to be.

My name is Richard Brennan. I'm with AT&T Network Systems. That used to be our name; I can't tell you what our name is going to be in March, so we're referring to ourselves as the "no name" company because we're one of the companies that are going to be spun off from corporate AT&T. We're going to be a nice little 20-billion dollar start-up company in March, and we will have everybody with a factory with AT&T come into our side of the company. So if it's made in the factory, we've got it.

Currently, I support the applications that AT&T is partnering with Pacific Bell for providing in California, so I do have a bit of a West Coast bias. But I will hopefully get over that and talk about things in general, and how they work in other regions of the country and, in some cases, how they don't work very well in other regions of the country. You can send me e-mail.

These slides — I don't have handouts for you — but the slides will be both on the CD-ROM and available up on the Net, hopefully by Monday, at www.image2000.com, which is our Home Page in San Ramon, California. They will be in gift format there, so you can pull them down as individual images and take them off the network.

What we're going to do is go through the presentation and then do questions at the end, so I hope to do about a half an hour of direct presentation and then take about 15 or 20 minutes worth of questions. We aren't really bounded on time, since I'm the next speaker also, so I can use up a little of my own time there.

What we're going to do is review ISDN and talk about the ISDN Internet providers and long distance phone companies. Just to review: ISDN is the new digital protocol, a new digital telephone line. It runs on the same copper pair that ran under the streets to get to your place of business, or your classroom, or to your home, but it is a pure digital protocol coming from the network that supports a multitude of services. It's internationally standardized, and it's really well-supported by the vendor community.

I think you should go out on the floor here and start looking around at the booths supporting dial-in connectivity. There are almost as many or more booths showing ISDN dial-in as there are showing modem dial-in. I mean, this has gotten to the point where ISDN is becoming the preferred mechanism for dialing up to the Internet.

Mac User magazine had a little bulletin, on the lower right-hand corner of the cover on this last issue, that said, basically, that ISDN is what you need to get onto the Internet. What you need in order to provide a link to an Internet service provider is a place where you can connect up.

Now, whether you're an individual user or an Internet service provider, the elements are the same: you need a connection to the ISDN Public Network, which is the global digital network; you need power — ISDN devices are not powered from telecommunications switches, so they will need local power; you need a function called a network termination; and you need a functionality called a terminal adapter. This will vary greatly, depending upon whether you're the individual user or small LAN site of an ISDN connection or whether you're the service provider site, but we'll get into that detail here as we go forward.

The ISDN's basic rate is basically the unit of ISDN. It's the set of channels that are derived off of this new digital connection. There are not three wires in an ISDN connection — there are three channels' worth of communications derived out of that same pair of wires. They used to run your old analog telephone, but now we can run a total of about 144,000 bits per second on the single connection to your home.

What we're going to do is aggregate those up into a primary rate interface for service providers, so that many people originating from basic rate connections can dial in to a service provider — and that could be a commercial service provider, corporate, or educational service provider — and get access to a gateway that provides them Internet access.

That's usually done over the primary rate interface — the initial increment of which is 23 B plus D, so 23 B channels, 64 KB channels, and one D channel, which controls what goes on in all the rest of the channels. In both the basic rate, BRI, and the primary rate, PRI, it's the D channel that tells us what kind of service is coming over that network connection. As you see here, on the primary rate I can have voice or modem connections.

By the way, to the digital network a modem call, even though it's data, is considered a voice-grade connection because it's carried as a series of tones over the network, not as zeroes and ones. When I say data, I mean pure zeroes and ones going through the network, like we would get from a PPP or a multi-link PPP connection, which we talked about just in the last session. We talked about equipment and interoperability.

If I want more capacity than that single PRI can provide, I then start stacking up those T-1 pipes, each one of which has a total of 24 channels in it, so 1 1/2 megabits at a time, I'm starting to stack up bandwidth. Ultimately, I get what's called an NFAS (Non-Facility-Associated Signaling) PRI. What that means is that there are then facilities or T-1s in my network coming to me as a service provider that don't have a signaling connection, don't have the green pipe, which is the D channel signaling information in the same T-1 as the calls are running. So the first T-1 will always have a D channel, and then we'll have 23 B channels.

After that, I can add more B channels — 24 at a time — without adding another signaling channel, up to some maximum of usually in the hundreds of channels that I could then run in to a point of service and provide connectivity.

Now at some point, I may say, well, that's an awful lot of communications to be running dependent on the continuous operation of that single D channel, so to provide an additionally reliable connection, I am going to put a backup D channel on the last PRI. So any PRI from the second to the nth PRI, or T-1 facility, could have this backup D channel.

So I've got two things: I've got the non-facility associated signaling, which means some of the PRIs don't have their own D channel in them; and I've got the backup D channel. That's the set of services that most of the Internet service providers build; and if you look at their literature, a lot of them handle numbers like four or eight PRIs, and what they mean is they handle four or eight T-1 facilities and then they can usually accommodate either facilities with or without a D channel.

They may choose to just go ahead and order four T-1s like the first one — each T-1 having its own D channel, that's an allowable configuration — but that means there are four independent facilities and they have nothing to do with each other. Or they could order four like we've shown here, with the middle two PRIs being the way I've shown T-1 number two here. So I'd have one with a first D channel, two with no D channels, and the last one I could optionally have a backup D channel.

That would be a very effective way of then building a service from the public network to your telecommuting hub if you're a corporation, to your student access hub if you're an educational institution, or to your dialable gateway if you're an Internet service provider.

If you look at the way PRIs are connected, they're connected from digital telecommunications switches. They originate just like a telephone line did except they're much larger-capacity. They run through — in the voice applications, they tended to run through PBXs to provide individual user connections behind either proprietary protocols or analog protocols or the ISDN BRI.

Now, some PBXs will support a PRI hub behind the PBX, so you might be able — if you are an educational or a commercial user you could put a PRI-connected dialable hub behind your PBX, and then you can share bandwidth with the voice calls that are running into your PBX. The reason this is good is because during the day you'll probably have more voice communications running into your PBX than data; during the evening, when people are trying to telecommute in, you might have more data connections than voice, and you might have no voice if there's nobody at work. So you could essentially spread that usage across the same PRI facility by essentially hiding your gateway behind the PRI. You can't do both at the same time in the same quantities because you're limited by the total number of channels you put into the PRI.

A more common service arrangement for an Internet service provider is to procure PRIs directly from a carrier — and that could either be from an exchange carrier, or a local exchange carrier, or an alternate access provider — and then they would hook up their connections using dialable phone numbers, directory numbers into the network. Anybody who wanted to access that service then would dial the directory number they gave you and get into their bridge or router from off the network.

Typical switches would include the AT&T 4-ESS and 5-ESS switches, and the NORTEL DMS. The switches might include Siemens' and Ericsson's, which you might find in the American network.

So this is the model that essentially we end up with: individual users dialing through an ISDN network, and the individual users have some kind of device, an ISDN terminal adapter, and they're dialing into the network and they're going to hit some kind of an access gateway box that is then connected to the network; the network there is then gatewayed to the Internet service and the Internet itself, usually through a very high-speed connection, typically at least a T-1 and often a DSP or 45 megabit-type connection.

Very commonly, the connection up from the network gateway to the Internet itself will be run as a frame-relay connection, which is a little bit more efficient than ISDN for dedicated connections. ISDN has the advantage that it is a dialable connection and can be routed essentially from anyplace that has a digital network capability. That includes most local phone companies; most of the digital PBX providers can upgrade their PBXs, and all the international carriers and international service providers are doing ISDN. In fact, in America we sort of lag behind the implementations in Europe and the Pacific Rim because we don't have directed policy telling people when they should do ISDN.

An important consideration in handling large numbers of channels is that PPP protocol, the protocol that's most commonly used for a synchronous network connection dialing up to the Internet. It was originally architected to run over one channel. And you just saw that the ISDN, the basic rate and the primary rate are built up of lots of littler channels.

So an issue is, "How can I take advantage of those multiple channels to do my Internet access connection?" Well, TCP/IP has an RC written here — the engineering task force — that's been widely adopted throughout the industry, and that's RC-1717, which provides a new protocol called MP protocol, multi-link PPP protocol. That protocol then allows multiple channels to be connected to a single TCP/IP session.

There's another, older method of doing that called "bonding." The difference between the two is that bonding uses a functionality called an IMUX, or an "inverse multiplexer," which

is essentially electrically-adjunctive and separate from the TCP/IP application. So the TCP/IP application sends one PPP stream out towards the network, and the IMUX does what we like to call slicing and dicing — it slices up that big PPP set of packets into smaller chunks, sends that over multiple channels, and reassembles them at the other end.

MP, however, understands that the network has channels and is an extension to the PPP protocol which understands channels directly in your application or in your gateway. Those two cannot talk directly to each other; you can't originate a call on bonding, and terminate it on MP. However, many of the boxes that do bonding also do MP, so sometimes you can have your cake and eat it, too. You just need to both agree whether you're using bonding for a multiple-channel call or MP for a multiple-channel call.

That's the kind of question that, as a service provider or when you're negotiating with a service provider, you need to ask. Which kinds of protocols are you supporting for connections with more than one channel? And you'll get different answers depending on the service offering. That's why you see pricing variations for single 56 or 64KB connections, dual-channel connections and multiple-channel connections. There are some boxes which support bonding but do not support multi-link protocol.

We'll show a few examples here of service providers. This is just an example of how I do my access in California; InterNex*Tiara is a commercial Internet service provider, and they've established point of presence in my local area. They're not in the same town I'm in — they're down the road a ways — but they are reachable on a dial-up connection through Pacific Bell's network, so I dial from a workstation. At various times I've used the Ascend pipeline devices, I've used the CombiNet, which is what I currently have in my home, and I've used AT&T telephones to do that. We dial through the ISDN network, and that terminates, in their case, on an Ascend Max hub.

Those are the kind of equipment combinations that you'd end up building a network with to support anything from four to 400 users. If it was a four-user network I might put something small like an Ascend 400 hub, which supports a four [inaudible] line, eight channels worth of capacity, up to the Max hubs which support four T-1s worth of capacity.

Gandalf, Network Express, [Teleosis], CombiNet, Cisco — those vendors will have other products which do very much the same kinds of functionality. You can mix and match — you don't always have to pick the same kind of hardware at the user end that you have at the ISP end. What you have to do is, once again, check that set for compatibility. Are we running bonding? Are we running multi-link PPP? Are we running Ascend's MP Plus protocol? What is the set of connections that, number one, I'm trying to make, and number two, that's offered to me by this combination of equipment?

One of the interesting ways of using the telephone network to build a service like that is to build a so-called "Internet centrex." This is built around the fact that in a telephone service a centrex was defined as a set of telephone terminations that could talk to each other without incurring any message units.

Now, back in about 1962, when this was originally designed, people had it in their minds [to have] a whole bunch of people sitting behind analog telephones in a single building, talking to each other in an intercom kind of a style. If you go forward about 35 years the connections are now digital, and in some locations they forgot to write into the tariff that they all had to be at the same address, so you have a combination of circumstances which lets a service provider go to a single digital wire center that's running ISDN and say, "I'm going to create a service called an Internet centrex. I'm going to buy centrex service from the local telephone company." In California it would be Pacific Bell.

[Then they would say], "I'm going to buy centrex, and I'm going to sell a service out of that centrex that is the combination of a centrex service and Internet access service. So I

become a centrex re-seller, and when you buy service from me I arrange for the line to be hooked into your home. The telephone company bills me, and I bill you for the sum of your Internet access and your telephone access off of that connection.”

Well, what’s nice about it is there are no usage charges from the telephone company for any of the connections within that centrex. So if I’m dialing from a home location into the gateway, and I’m on the centrex — or from a small business into that gateway — there are no usage charges. If I’m in the same building, obviously there are no usage charges. However, if I’m outside the centrex I can still subscribe to this commercial service, but now the telephone company is going to charge me measured units most of the time and then I’m not getting my phone line through the Internet service provider.

So you can sort of play several games here at once, but this is one way of getting around the idea of having to pay from one to four cents a minute for your connectivity time to the phone company, as well as whatever you’ve contracted for your connectivity time from your Internet service provider. So everybody wants their penny here, and what we’re trying to do is optimize the set of services to accommodate that.

When I’m building access it does make a difference [in terms of] the sort of service I want, and some of the issues are around security. One of the people that I’ve worked with works for a large petrochemical engineering concern, and they were concerned about putting fully routed connections into their telecommuting network. Their concern was this: I have a device that has two B channels for data; I can dial those two B channels in different directions, one of them up to my corporate telecommuting LAN-access gateway, one of them off to somebody who I didn’t really want to have get access there, and without a lot of problem, I might be able to route between them.

That was viewed as being not necessarily the greatest thing in the world for corporate security, so some of them have preferred to use filtering bridges to set up those kinds of telecommuting gateways. Now, what you can do is — you’re not, once again, limited to only bridge connections or only routed connections. Generally, a lot of the hub gateway devices can handle either type of service, so there are performance characteristics that come with each kind of connection. And those are the kinds of things that you either want to discuss with the gateway hardware manufacturers, if you’re setting up the service, or with your ISP if you’re buying the service. Depending on whether you’re getting a route connection or bridge connection, you may get a different cost point and a different utilization factor off of that network.

One of the interesting things is that just because I have a digital connection to my network, it doesn’t mean that all of the calls have to be coming on digital paths. Some of the equipment can handle incoming calls that are sourced both from digital endpoints, like ISDN terminal adapters, and analog endpoints — I think they use something called a modem to do that.

Some of the digital endpoints with only digital conductivity can handle both your incoming modem traffic and your incoming digital ISDN traffic. This gives you really clean data-center installation because I don’t have to have one massive rack of modem pool equipment and another rack of digital access equipment. I can compress that down, only have digital access, get some integrated network management tools running here, and have all of my commuters dial the same set of numbers, no matter which capability — voice, which is modem traffic, or data which is PPP traffic — is coming into my data center.

It’s a very clean installation, and one that really makes telecommuting work nicely because I don’t have to change my published numbers; people can change from modems to ISDN at home and still dial into the same location. So it becomes a sort of a unifying part of a telecommuting or remote-access strategy to be able to do this.

M: [inaudible]

Richard Brennan: Well, it looks at the incoming call and says, "Is this incoming call a voice-bearer capability or a data-bearer capability?" If this is a voice-bearer capability, I know what that is — nobody's calling me expecting a phone here, this a modem call. Modem calls are voice-bearer capabilities; modems convert the zeroes and ones of your computer into tones running in a voice-bearer capability.

If the next call comes in and it's a data-bearer capability, it says, "I know what that is, that's going to be a PPP call," so it terminates that and then it negotiates protocol. Then it says, "Is this a single-channel PPP call or is this a multi-channel PPP call?" and it should be finding out if there are some other channels dialing me that are going to be associated with the same session. The gateway products can do all of that intelligence and unify that. Some of them do it with DSP technology; some of them do it with brute force with modem chips in the gateway, but you're getting the same functionality.

With local exchange companies, don't just count on the fact that if you're in one of the seven larger Bell regional holding companies that those are the only people that have ISDN. Both Rochester Tel, up in New York, and places like the [Roseville] Telephone company in California are very much in the forefront of ISDN deployment. So a lot of the small independent companies also have been doing some ISDN.

There are some of the smaller independent companies that have really gone gangbusters on making ISDN available. Pacific Bell — not just because I live there, but I think it's fairly well recognized that Pacific Bell has one of the better sets of service offerings both from price standpoint and from availability standpoint, perhaps not only around the country but perhaps around the world.

[I want to discuss] what you're going to get from your telephone service provider. Really, you're starting a stack of things here: I need an ISP — an Internet service provider — and they're going to have to have connections to a public network; I'm going to have to get connections to a public network; and if I'm not located in that carrier's area, I'm going to have to get connections to a long distance network. So we're going to go through the whole set of services here.

You need a U interface and a 2R interface coming in from the network. This is the protocol that now allows the ISDN line to terminate. This is where the term [2B12] U interface comes from — two binary information elements and one [inaudible] or four-level signal. This is the ASCII standard. So that 2R interface is what replaces the analog pair of wires that was running the tone-based signal to your home.

What you get into is a distance limitation, which says that if the telephone company cannot get service to you within, say, 15,000 to 18,000 feet, they're going to have to add electronics on the line to get that signal to you. So this constrains your ability to be a service provider in some cases, because some phone companies bill you extra for making those lines reach.

Pacific Bell has a policy that they will provide the electronics; they averaged it into their tariff cost so they will provide extra electronics. You see at the bottom, for getting past that arc, it says that's where I can serve from the central office switch.

So if you hear of people being in ISDN blackout areas, it's for one of two reasons: either the central office switch has not been upgraded to provide ISDN capabilities, which is "a billion dollars here, a billion dollars there" kind of project in California, or your copper wire is running too far under the street for that service to be able to reach you.

There is a — anybody who quotes footage on ISDN is lying to you — there is a 42 dB of gain/loss budget on the pair, and it doesn't like being tapped; so the answer is that it always depends on what your copper looks like, as to how far the ISDN can go. A reasonable engineering guess is 15,000 to 18,000 feet; after that, if you live up in the hills, down the road, or around the canyon you're not going to be able to get an ISDN line without some extra electronics. And in some service areas, they will bill you for that extra electronics, and it could be as much as \$1,200 a line.

The T interface is a very short interface — it's what most ISDN PBXs provide. It's a four-wire short interface, and it's what most equipment is built to because it's a very international standard. Only in America do we see a large number of devices with the built-in two-wire U interface standard. Most other countries, because of regulatory differences, have the NT-1, or two-wire to four-wire conversion provided by the phone company.

We in America had to be different so we said, "That's customer equipment, and we let you pay for it, buy it and install it yourself." So the T interface is the four interface. Remember this: T for two pair, that's what most of the devices will be running. If you heard the equipment session earlier, it does make a difference if your device has a U interface on it but does not give you back a T interface — that is the only device that can be on the ISDN line.

If you're looking at the back of the box, it takes U interface and also gives you T interface out. That means you can add extra devices on an ISDN line. If you have a stand-alone NT-1 that takes U in and gives T out you can have up to eight devices on the line, depending on the switch implementation.

Here are the variations you're going to need to ask your telephone company about. From the PRI you will be connected, in most cases, to either an AT&T or NORTEL switch. I think there are also some Siemens and Ericsson switches in the public network. For basic rate, it'll mostly be the same — AT&T and NORTEL.

Then there's national ISDN. National ISDN is an attempt to standardize the switch-to-user equipment interface across all manufacturers of computer hardware, and all the switch types. The first version of that is called National ISDN 1, and it came out in late 1992. It is just now being widely deployed.

One of the problems in the phone industry is how to rewire 20 million homes and several hundred million phone lines. It takes a while — and a few billion dollars. So we're just getting into the NI-1 time-frame. Most local exchange companies are now either provisioning NI-1, or customized ISDN, depending on the switch type to your users and to your implementations.

You need to know which it is. You need to know which kind of equipment you're buying and whether it supports NI or custom or both. NI-2 is being loaded into the switches right now, and service providers will start adding that to their offerings when it becomes readily provisionable.

Then there's NI-3, and they're renaming them NI-95, NI-96, and NI-97. So, like all good standards, they keep changing, so they keep engineers employed.

[There are some] must-know parameters. You need to know your customer NI; you need to know your switch type; you need to know what kind of service you're getting; and you need to know, on a basic rate, what kind of SPID, or "service profile identifier," and [the SPID] is an absolute mandatory element that you must demand of your telephone service provider.

From the interface service provider, all you probably need to know was the IP address range that you're getting from your service; what kind of protocol they're accepting; and [whether it's] PPP or multi-link or bonding. But these all go together to say that in order to dial a complete connection, I have to know all of those things.

Then, of course, what happens if my Internet service provider and my user are not located in the same service area? I need to dial long distance, and that brings up a whole other set of issues. It says here's what the network really looks like. There are really three networks involved here: there's the 56/64 KB network, which is where our voice calls currently run; there's the X.25/X.75 packet network; and there's something called the SS7 signaling network. Those networks all need to be connected up between carriers if your call is going to go from one carrier to the other carrier and come back down to a user.

In fact, they need to be connected correctly within your carrier's own network in order for you to gateway between different switches in a single carrier's network. People are just now starting to get Signaling 7 conductivity, and what we call "64-clear," [which is] the ability to run at 64,000 bits per second instead of running at 56,000 bits per second. 56,000 bits per second is what the old voice network has run at for a long time, since they first started putting digital equipment in the network.

In order to get the full bandwidth of ISDN we have to change to Signaling 7, and do a lot of changes in the network to open that capacity up.

If we are running packet mode — which is not wise to use for TCP/IP, although that's really where it originated — you need to have a packet gateway to your packet carrier that supports a relatively high-bandwidth connection.

When you look at the service providers, each one of these service providers has to buy connections from the local exchange carriers and then put in the necessary facilities — 56 or 64KB facilities — and the Signaling 7 gateway connections to be able to handle your calls. So just because one carrier has a 64KB connection to your telephone switch that your local phone company has in your town does not mean that the other two have the same connections; it is very possible that they have not yet implemented in 64 KB, but they might be implemented in 56 KB.

We do a lot in testing here by trying the calls, first using one carrier, then using another carrier, then dropping back to 56 KB and trying it again, and eventually the call will generally get through from most exchanges in the United States. There's some digital connectivity in almost every local exchange.

With international — they've been running at 64 for a long time; they can't figure out why we're still so hung up on 56 KB.

Another issue is, who can talk to whom? If I originate on a voice-bearer capability — I don't care what kind of switch it is, we all know that no matter what kind of network I'm on I can talk to somebody else on a voice-bearer capability. So if I originate voice, it can go to voice behind any analog or digital exchange — it doesn't make any difference. We know that works.

If I originate in a 56KB data mode, that's where we have the most connectivity right now in the United States. I can terminate to a 56KB data mode whether or not it was ISDN. There are older switch 56 connections — switch 56 and some DDS-type services, and some two-wire switch 56 connections that were proprietary — but I can terminate to those, one channel at a time. Remember: ISDN has two B channels, or bearer channels, while those 56KB services only have one channel.

Now, what's interesting is that I can also connect to somebody who's running a 64KB connection in what's called "restricted mode;" so if I originate in 56KB mode, I can talk to somebody else who has a 64KB connection. But if I have 64KB connection that I originate at 64KB, I can't always talk to somebody who has only a 56KB connection; I have to change my call origination down to a 56KB bearer capability, which is possible.

When I have ISDN I can either choose 64 or 56KB to originate my call. If I originate at 64KB, the bottom line there, I can only terminate when the entire network — from the local exchange up to the access tandems to the point of presence for the exchange carriers, the long

distance carriers, all the way through their network and all the way to an international gateway, then all the way to the other side — that's all got to be 64-clear in order to make a successful 64KB call.

To make a 56KB call I just need a data-grade pathway through all those connections; and those might not be Signaling 7, they might not be ISDN, but they'll all be digital. So there's a much higher likelihood of connectivity in the United States.

A lot of us who do this just leave our equipment at 56 and don't worry about the last 8K. As a [inaudible], it's not worth worrying about, because the speed I'm getting then in comparison to modem speeds is so beneficial that I don't worry about trying to get that last 8K out of the network connection.

M: [inaudible]

Richard Brennan: It knows what bearer capabilities connect to what. The network knows that; it knows what facilities a 64KB call can transit, what facilities a 56KB data-bearer capability can transit, and what facilities an analog voice-bearer capability can transit. In Signaling 7, in pure implementation, all of those bearer capabilities can run down the same network. In Signaling 7 the network doesn't care what kind of connection you have; it's where we don't have a full Signaling 7, 64-clear environment that you have to worry about this. Now what this does is this constrains how you can get access to an Internet service provider, and over what distances, and at what speeds.

If you want to get to some very good starting points and pointers on this, I highly recommend the authoritative ISDN Home Page, which is Dan Kegel's Home Page at Cal Tech. The service providers — you can go to [inaudible], or you can go to att.com, and mci.com, sprint.com, for their services.

I'm just going to shift gears here and show you a little bit of what Dan's Page looks like. The quickest way to find Dan Kegel's Home Page is to go up to WebCrawler, put in "Kegel," and space, and then "ISDN," and it'll come out as the top thing on the list. This really has the largest centralized gathering of information.

[I also want to mention] new information about engines and terminal adapters — they're breaking the \$300 price barrier. In fact, I believe that's very conservative — one model of the Motorola *BitSURFR* is already priced at \$249 at Fry's Electronics store in California, and there's rumblings that there will be a Christmas special with an even lower price than that. So TAs don't have to cost any different than modem technology, given that they typically run five times as fast.

If you go into the ISDN hardware side of Dan's pages — they assured me this was a fast connection — it must be popular right now — what you find is perhaps a much larger list than you might have expected for hardware providers. Many of those hardware providers are also gateway hardware providers. Look at the large system providers. Cisco, as you may know, just acquired CombiNet, so Cisco and CombiNet are working together and those products have been renamed the Cisco *Pro ICM* devices. AccessWorks was bought by 3Com, so 3Com is marketing the AccessWorks boxes. Ascend, I believe, provides both hub and individual user devices across a large range of sizes.

So here's this long grocery list. Why don't we start questions while I'm pounding the keyboard here? Any questions first?

M: [inaudible]

Richard Brennan: NT-1 — in the United States you do have to buy the NT-1. In all the reasonable countries of the world it's part of the telephone company, but for you today you get to buy it. It can either be inside the box — it's functionally separate — but it can either be inside the box, and then the big question in terms of buying criteria for you is does it give you back a T interface that determines whether or not you can provide another connection off of that?

M: [inaudible]

Richard Brennan: In some, yes, it is included. Most of the vendors in the United States, to simplify the installation, are bundling products usually [inaudible] either with or without an NT-1. That's on the end-user device. Now, on a PRI-connected circuit, you don't have a separate box, called the termination; what you have is the typical functionality that terminates at T-1, and the functionality is there, but it's not a separate, small, cigarette-pack size box like you get in the individual user devices.

Here on the East Coast what I've found is that the number of Internet access providers is not as large as back in California. There are dozens of Internet service providers in California that are setting up small services where you can buy access where you can buy service on an individual user basis.

The typical going rate is about \$30 for 30 hours of usage a month as an individual dial-up user. Now you match that with my ISDN line charge, which from Pacific Bell was \$37 to install and \$25 a month; then in Pacific Bell's territory I get free local calls, flat-rate local calls, from five in the evening until seven in the morning. So I can dial InterNex*Tiara — which is still within 12 miles of me — I can dial them at five o'clock on Friday night and stay connected until 7:59 on Monday morning and incur no telephone charges at 128,000 bits per second. That's fairly good service, you know. So it is doable. I wish I could say that the service was equitable throughout all the regions.

Here is this long, long list of hardware equipment types [on Dan Kegel's ISDN Home Page].

M: [inaudible]

Richard Brennan: InterNex is charging me \$30 a month for my basic access — it's for the first 30 hours, and then there's an increment after that. I exceed that most of the time, but then my telephones — I haven't gone through my \$25 service charges because I make pains to make sure I'm not calling during the day when that is a message unit. In Pacific Bell's territory it's four cents to originate and a penny a minute, so it costs me sixty-three cents per B channel per hour to stay connected. Even if I'm telecommuting, this is not going to break the bank, you know, so it's \$1.26 for 120KBs for an hour. So you can do eight hours of corporate access and not have an outrageous penalty for staying connected.

I'll just look through the list here. These are the terminal adapter providers, and you see that big names are here — Cisco, 3Com, Ascend, IBM, Motorola, U.S. Robotics — it seems like I thought [U.S. Robotics] made modems — nothing in ISDN is a modem. I detest the terms "digital modem" and "ISDN modem," but it's becoming popular in the press release wars and in marketing. There's nothing going on in there that's modulating and demodulating anything, so it is not a modem. AN ISDN terminal adapter maps straight zeroes and ones of your computer into the zeroes and ones of ISDN, unless it has a modem or DSP functionality for emulating a modem or a fax/modem capability.

[Inaudible] is a DSP that can go right into your PC computer and can emulate a fax/modem as well as talk to your Internet service provider, using PPP protocol in pure digital, so I could be sending a fax on one channel and be up on the Internet at 64KB on the other channel. That's a fairly nice capability out of one line. You'll see a lot of these.

Routers and bridges: ACC, Ascend, Bay Networks, Cisco, CombiNet, [Digiboard], Gandalf, the Network Express — the same players that you've worked with in setting up your routers and your bridges. Every one of them is now building ISDN gateway devices, and some of them that are perhaps not as traditional — people like [inaudible] are coming on board with new products that allow — [inaudible] has been very big in the Macintosh networking arena, and they're the kind of vendor that is now adding ISDN to the set of applications that they're able to support in networking.

More questions? Yes?

M: [inaudible]

Richard Brennan: How much do you want to pay? I have seen cards going for as low as \$250, and I've seen cards going for \$2,000. When you buy a \$2,000 ISDN board, what you do is basically plug in a very stupid \$900 computer as a peripheral to the board. The board is handling everything — it's got a fast processor, it's got many megs of memory, it's an intelligent co-processing board to which you can plug a very dumb computer.

At the \$200 level, which I think we'll see here either at Christmas time or very shortly thereafter, what you get is a very low-functionality board. These boards have been real popular in Europe now for a couple of years. That's where you're using the strength of the computer; essentially you use bus cycles in your CPU to run the ISDN communications. Remember, the computers are not used to running three or more logical sessions out of your computer at very high speeds, so they're having to gear up to handle that. It takes the current generation of better processors, the better communications toolbox or driver capability to be able to support that. So the less you pay for your ISDN interface, it turns out, the more CPU time you burn in your computer.

I'd like to get back to the ISP service. The basic thing that we're looking at here is setting up — I want to call it an "I-squared SP," ISDN Internet service provider. Basically those people are all buying the hub-type products, the network managing them against servers, which are then able to offer services. I'm involved in community-based services in California such as CityNet, and [C-4Net] up in Northern California, which is doing that on a community access basis.

So if you can get a small grant to put together your own connection as an ISP, you can then become a "public access network," or a PAN network. We've seen some literature from Smart Valley in Silicon Valley about setting up those kinds of networks. Alternatively, you can find space on other people's networks that are already built as commercial networks and set up a virtual community network using capacity in what was a commercial ISP, because a lot of that community access is done off-hours. So it's very beneficial to allow community members to access into the service node off-hours, where you have less of the business load that would be tying up their servers and gateways.

For setting up an educational or a corporate network, basically you have to decide how much of the business you want to do yourself in terms of administering as a corporate or as an educational system administrator. How much network management tool do you want? What kind of capacity do you think you want to provide? What types of dial-in capability are you going to support? Are you going to support the evolution from modem technology up to digital? Are you going to try to get everybody to go digital at day one?

My neighbor across the street, who works for a large petrochemical research installation, started out ISDN dial-in with only a few small stand-alone terminal adapters. When the senior scientists at this particular company found out that they could do their literature searches on-line to a database that has all the graphical text search engines built into it, he could no longer handle the load individually. He had to give it over to corporate telecommunications to start building bigger and bigger service.

He showed them a videotape of his workstation inside the research area, showing him accessing this application, and then it showed him dialing in from home, and you could tell which one was the home application because the access was faster than through the corporate network. Now, you say, how could a dial-in connection at 128KB be faster than a 10 megabit connection to his desktop? And the answer is, well, it wasn't really to his desktop, it's past his desktop and it's routed through a couple of the buildings in the network and it's congested; so a congested local area network in a corporate environment or an educational institution may be very much slower than dial-in access to a gateway hub located right next to the server that you're trying to get to.

So less is sometimes more in networking here, and that's the kind of thing that causes people to really like to be able to dial in to corporate and educational networks.

The other issue is, how am I going to access the Internet? By dialing into my network and gateway out to the Internet? Or am I going to dial into a commercial Internet service, and then gateway back into my corporate network? This raises — there are lots of vendors with plenty of solutions for you.

[There's] the issue of firewall and filtering servers. How do I allow the right level of access in and out of my network to the public Internet? And how do I set up this mixture of people in my network dialing out, and people from outside trying to dial in? So you can set it up either way; they both have very excellent applications in usage within the network. You may want to do some of both, but make sure you understand. You don't want to just open up a gateway to the Internet and allow everybody to dial in to see what your corporate research looks like; nor, perhaps, do we want to allow little Henry from the seventh grade to dial out into everything that's available in the Internet. We don't have all the books from our libraries in the middle school library, nor do perhaps we want everything on the Internet flashing up on screens in the middle of the seventh grade lab period.

So with that, I'll take any more questions, and then we'll get ready for the last session here, which is on getting ISDN to the home.

M: [inaudible]

Richard Brennan: Surprisingly, very few of the [inaudible], I think, have become Internet service providers yet, although we hear announcements coming that they're going to do that, and I would imagine that will be the mechanism for how they do that. I have not seen explicit plans to do that.

Mostly it's what we'd call "centrex resellers." An Internet service provider signs a contract with a local phone company to become a centrex reseller. They've done this in the voice arena for quite a few years, where a person who owns a building would buy centrex and resell it to all the tenants in the building as a shared tenancy. An Internet centrex is a shared tenancy centrex where all the addresses didn't happen to be at the same spot.

I see it more from independent Internet service providers. The expertise required to be a good ISP and to provide a good level of support — it's not immediately intuitive that this is the same level of expertise that you need to run ISDN telephone connections. So those are

two different businesses, and they both sort of lean on each other for support. I'm not sure that either one can take over the other's business.

M: [inaudible]

Richard Brennan: I'm sure that when [inaudible] start getting enough connections to be able to offer those services this will be something they will jump on. Usually they will have fewer switches, and they will be more recent switches, so they will definitely be ISDN-capable. The question of how they can cost-effectively offer that to businesses, and especially to individual users, will determine whether or not that's a successful strategy. And that's a regulatory issue, so you never know the answer.

Any more? I thank you. For those of you who want to really do this yourself and hear a third variation on this talk, we're going to talk about ISDN to the home in the next session.

INTERNET TECHNICAL ISDN: AT HOME

SPEAKER

Richard Brennan

Technology Manager, AT&T Network Systems

Richard Brennan: I'm sure this area will cause a few questions. My name is Richard Brennan, and I'm with AT&T Network Systems; at least that's who I thought I worked for until AT&T announced this recent breakup into three companies, so — as we refer to ourselves internally now — I'm with the “No-name Company,” or perhaps some symbol and the “Company Formally Known as Western Electric.” And it will not be Western Electric, it will not be anything but AT&T and we will have a new name, probably in March when we emerge as a \$20 billion start-up company. And we will be doing a stock offering at that time, so I'm sure they're going to have a name for us then.

My role is as a technologist. We are the technology partner of a lot of service providers, in bringing ISDN to you and to commercial service providers, to businesses, educational institutions, and my role is to support Pacific Bell's efforts in California, and so I betray my West Coast origins by knowing a lot about what's going on out there, and not quite as much here except what I hear via the rumors of what's going on here.

Now, the unfortunate thing is that I think what's happening on the West Coast may be a little bit ahead of what's going on here, so it's more of a goal rather than something that's happening in the same quantities; although we do hear that in some locations out here you can realistically hope to get quick and easy access to ISDN, but it is not at all pervasive.

My first question to the audience is going to be, how many of you know what ISDN is to a level of comfort that lets you discuss that? How many of you wish you could get something like high-speed access to your home, like ISDN? And how many of you already have ISDN to your home? One, two, three, four, five, okay. Those are about the right ratios, I think. Everybody wants it, and five percent of the people may be able to get it. The numbers are not going to remain like that, because the technology is becoming pervasive and it's more of a regulatory and economic issue as to the availability of ISDN.

What I'm going to do here is a little overview of ISDN for those of us that don't have a full understanding to discuss the issues, and then we'll talk about how to really implement it in your home; and I'll use, as a framework for that, my experience as I set it up in my home.

ISDN is nothing more than “international standard for a digital telephone” line, but when we say that we have to divorce ourselves from the thinking that somehow a phone line meant a pair of wires and a thing at the end that looked like a telephone and had a phone number to it, because the new digital model doesn't look at all like that. How many devices I have on the line is something that's contained in the software relationship; how many phone numbers I have on that line is a software relationship; how many different types of conversations I'm doing on the line — voice data, packet data — that's controlled by software, so it is very non-linear, and for that reason sometimes we get confused because you can do many things at the same time, and yet we're trying to talk about them one at a time. So remember, we can do lots of different things.

What we're going to talk about here is the set of things I need to bring ISDN into the home. ISDN, for most of us, will be delivered by our local telephone company, so whoever is providing your phone service to you today is probably who, in the immediate near future, is going to be providing ISDN service. Now, that's not to say that sometime down the road a cable television company or an alternate access provider or someone else might not be able to

provide ISDN; but I think those are awaiting some regulatory processes and decisions and some marketing decisions. They are quite a bit further down the road than you might think, and so probably we're looking at the local phone company as being your source.

Now, their line might be resold to somebody who's marketing it to you, and that's a slightly different technical issue, because it's still coming from the telephone company switch. The good thing about ISDN is that it comes into your home on the same kind of pair of wires — in fact, it could be the same pair of wires — that ran your analog telephone service.

Now, I said "could" because I'm not going to recommend that everybody go out and get rid of their analog telephone and put in an ISDN line, for one minor reason. You see this little power unit down here? ISDN lines are all microprocessor-controlled devices, and they have microprocessor-controlled devices on them and they don't run out of the battery power that is provided by the phone company like your analog telephone does.

So when the hurricane hits — or in California, when the earthquake hits — and the power goes off, you will not have telephone service on an ISDN line because your local power will have gone out. Of course, you don't have power to your computer, either, and I don't know how you're dialing the Internet... But that's another issue. So I would always recommend that for home use you leave in your analog phone as your first phone line and put your ISDN line in as a second or later phone line. In my case, with a wife and two daughters, there were three phone lines and you can imagine who did not have access to a telephone line. The Internet is not a reason that we should interrupt social discussions around my community. We've rectified that.

So the elements that we're going to look at, [and the ones] that you're going to need — these are functional elements. [The first is] the network termination. The network termination is an electronic piece which does nothing for you; in all of the reasonable countries of the world — the network termination is here, labeled NT-1 — that is part of the telephone company's equipment. In the unreasonable country in the world, one with a market-based telecommunications policy, you get to buy it. So you will get to purchase an NT-1 even though it really does nothing except change the two-wire connection that the telephone company ran under the street to your home or to your business into a four-wire connection, which is the international standard for delivering ISDN within your work group, within your home, on your desktop. So the four-wire connection is what runs inside the home.

On an ISDN line we can derive channels, so there are not free wires on an ISDN line, there are free channels in the ISDN line that's going to be pulled into your home. Now, think of your existing phone line; it only has one channel. I mean, it has one analog capability and you can either be talking to Aunt Millie or you can be dialing up to America Online, but you can't be doing both. You can only do one thing at a time. You say, "Well, it has extensions, and all of those people who happen to pick up those phones — they are not additional phones on the line, they are really additional handsets all connected to the same communication stream. You're not getting multiple conversations.

ISDN can support multiple conversations, so I could be talking to Aunt Millie using a voice capability on that top channel we call a B channel there and at the same time I could be using the second B channel to dial up to my Internet service provider at 64,000 bits per second — that's two-and-a-half to five times the speed that you're going to get from a modem — and at that same time I could be doing an electronic mail message in X.25 packet data service to my electronic mail delivery service.

So I could be doing three different communications using three different mechanisms to three different destinations; you just can't do that on an analog line. That's the power of ISDN. It's all digital, it's standardized for all of the communication vendors — you're going, "You say all, there must be somebody who's not," — but essentially all of the communications hardware

vendors you're going to see out on the floor here are building products to suit this standard. It is the standard for digital connections over the public network.

Now, we get into some considerations here. You saw that there were multiple B channels; one of the things that I have to ask when I'm going to sign up for some service and pull ISDN into my home, I say, "Well, where am I going to dial to?" And usually I'm going to dial one of two places: either a corporate local area network or an educational local area network. So I'm going to dial a gateway at my company or my school or I'm going to dial into a commercial Internet service provider — and, as I said, we have two B channels there — so one of the first things I say, is "Well, gee, can't I stack up those two B channels and get a service that's 128 kilobits worth of service?" And the answer is yeah, you can, and there are two methods for doing that.

The older method is called "bonding." Bonding says that I'm going to take those two channels and I'm going to stack them together and give that total bandwidth to my PPP session, which is the session that's going to connect me up to the Internet. But that function is totally separate from whatever product I was using that's originating my dial-up LAN session. So I've got the same connection whether I'm dialed up to my corporate LAN or whether I'm dialed up to the Internet, and for that function the IMUX, or "inverse multiplexer," says I'm going to take one stream that's my packets from my PPP session — which is how I talk to the Internet — and I'm going to divide those up and split them amongst multiple B channels.

It used to be, a few years ago, that IMUX was an entirely separate box and you backed it up behind a router in your LAN-bridging world and said, "Now I'm going to divide that up separately." Well, there's a new protocol out, as some of you mentioned, and that protocol was just published in 1994 and it's called "multi-link PPP." And that says that my LAN application, my software — that's my TCP/IP communications software that lets me communicate to the Internet or lets me communicate to my corporate local area network — is going to understand about these channels. Well, before it didn't know about them; it thought it was delivering one big pipe. Now it actually knows about how it's going to divide up the packets so that it can talk over various links. Why is this important to you? Well if you're going to go out and buy a piece of equipment that you're going to use at your home, first you have to have an idea of, "Who am I going to dial to?"

Let me back up to modem technology. If you went out and bought a 28.8 modem and said, "This is great, now I have a 28.8 modem, therefore I can dial everybody in the world at 28.8, right?" No. If they don't have one too, you aren't going to talk to them. View this as the same situation; if I buy a device that talks bonding only, I better find myself an Internet service provider or a corporate LAN gateway or an educational gateway that talks bonding. If I buy a device that talks multi-link protocol - [which is also called] MP — I need to make sure that my commercial gateway, corporate gateway, or educational gateway is talking MP.

So that is a primary decision point in what you would decide to place on your desktop for getting ISDN in your home and then gatewaying to some external service. Oh, and by the way, if I wanted to talk voice there's a number of ways I can do that, too.

So here's sort of how this network looks. I can have devices that do plain old telephone-type service — you know, my beige, government-issue 2500 set-up there — and also a data connection to my PC; or I could have a nice digital set, and it also has a data connection to my PC; or I could have a data-only device called a "terminal adapter." Terminal adapters and ISDN replace the functionality of a modem in the analog network. And all of those could be dialing in to some point of access, and that point of access is either going to be a commercial Internet service provider, my corporate LAN or my educational institution. And I can pick and choose some variations as to how I connect here.

Let's look at some of the ways we could connect up. The kind of equipment that you're going want to put in your home is going to depend on — you know, you have to ask yourself the hard question, "What am I really trying to do here? Am I just trying to access the Internet at high speed or am I trying to set myself up in a service business where I really have a home office and incoming phone calls are one of the most important things I have, because that's how I get all my business?"

Well, if I'm doing mostly voice and a little bit of data, I might want to put a digital set in my home, because that then offers me a high-speed data connection to my PC. That might be a viable set of services. If I wanted more data capability, higher bandwidth data perhaps, and two channels instead of one channel of data, and I was willing to settle for just an analog telephone set, I might choose a different configuration based on a board that we call the PCTA, the "personal computer terminal adapter," and it has an RJ-11 jack [which is] a voice telephone jack that lets me plug in my old powder blue, trim-line set into that board. But there's other variations.

M: [inaudible]

Richard Brennan: Yeah, but I don't think that should do it. It should still click.

Okay. I can pick another type of terminal adapter that would supply a mixture of both voice and high-speed data services from various vendors. This is an AT&T product; there's a Motorola *BitSURFR* product, and it's very similar to that. And I could then say I could support both voice and data kind of evenly, or I could just say I'm going to do data only, I'm just going to access the Internet. That determines what kind of equipment I want to pick on my line and it determines how I'm going to order my line from my service provider or my local telephone company.

Now, there's more variation here because I can start doing multiple things on the line. Here is a device that's got a telephone and a fax modem plugged into the back of an ISDN adapter. Faxed phone calls are voice phone calls to the network; modem phone calls are voice phone calls. Remember, modem and faxes send their information as tones down the network, and that's a voice grade of service. Even though we think of it as data, it is not to the network — it's voice tones.

So in order to send faxes and modems to people at the other end of the phone call who don't have ISDN, I need a method to convert my fax or my modem information into digital information, but carried on a voice capability just to the Net; and that's what this terminal adapter does by supporting an RJ-11 jack on the back. But at the same time, in another B channel, I can be supporting a 57.6 kilobit data connection, so I can do a data capability out of my COM port at the same time I'm doing a voice capability from my modem. This is confusing, because you can do many things at once.

Here's a device called the IBM *Waverunner*. Unfortunately, I checked at the IBM booth today and they don't have them running at the booth, but they do have the literature. The IBM *Waverunner* — say, what if I needed a product that I could talk to almost anybody on? I need a product that I can talk directly to a digital Internet gateway, and I want to be able to talk on two B channels. The *Waverunner* will do that. It's a PC board, but it will talk down both B channels to your Internet service provider, so I could get a 128,000 bit per second connection to the Internet.

But what if I wanted to talk to this AT&T telephone over here? This AT&T runs an asynchronous connection out of my COM port at 57.6 kilobits per second; well, the IBM *Waverunner* says, "Yeah, I can do this protocol." It's called V.120, and it is the same for

asynchronous ISDN phone calls as V.34 is for high-speed modems. [It's the] same relationship of the protocol to the telephone capability, and so we can talk there.

So I'm talking two B channels to the Internet, or I could talk one B channel of data to that phone and one B channel of voice to that same phone. The same phone number, two different things. But then the real kicker comes and says, "What if I want to talk to somebody who doesn't have ISDN, but they've got a modem?" Normally you'd think that meant you would have to have a modem somewhere. The *Waverunner* gets around that by using a DSP chip on the board to pretend it has a modem, to emulate a modem or a fax modem capability. So it says, "Now, if I was a modem, I'd have sent a signal that looked like this after it was digitized." It inserts that digital signal right onto the ISDN line, and then you can dial to a distant fax modem or a distant data modem as well as the ISDN connectors.

So that answers the question, "What would I do at my end to be able to talk to all the different kinds of endpoints that I might want to dial to?"

The other side of that equation is, "Can I call up [inaudible]? What if I wanted to just set up a connection between my corporate or educational gateway and my home or my dormitory for LAN access?" That could be Internet access gatewayed out of there, or it could be just for the kinds of computational things we're going to do on a TCP network, in a school. I might use a device like that Cisco *Pro*. That's the old CombiNet boxes that — Cisco just bought CombiNet, who has been a provider for quite a while in ISDN, and so Cisco's one of the major router manufacturers in the LAN area. So I would just put that box in and I would then have a very short local area network in my home. And perhaps it would be no additional wiring in my home, because I'm just going to run that new interface line, that two-wire line, to the Cisco box. It has a power plug that I didn't show here. And then I'm going to have a data connection, which is just one patch cable between the Cisco box and one computer. That's a very efficient and almost no-wiring solution for my home, and that is a connection that would give me good access into this kind of a corporate or educational environment.

What if I want deals that are more sophisticated? This is what I've actually wired at home. My daughter was complaining that from her Mac in the bedroom she couldn't spool her print jobs out to the laser printer in the front room; this is what 13-year old young ladies want to do these days, so it's the truth, thank goodness. So I decided to wire a local area network within the home. Well, companies like Sonic Systems, which is what I've used here, have these little mini-hubs. I picked mine up for \$159 and I've wired three bedrooms and my computer office — which has both a Mac and a Windows machine in it, and the laser printer — and we're all up on this little mini-hub and essentially now I've started wiring my home for local area network connections.

And once I've put that in, I took a little bit of care to wire that around. I made sure I used some good quality Category 5-type cable, which you can get down at almost any electronics store. I don't know if Radio Shack carries it yet, but I'm pretty sure they're getting pretty close. And I made sure I had nice straight runs all back to — I put the hub in the closet by the door that also has the hatch where I can get into by basement, so I can get under there and do wiring work on it, and then I plugged it in and I tried a couple of different boxes.

I used that [H&T *Express*] box and I've used a Pipeline, and I'm currently using a CombiNet box there that allows any of those computers on that little local area network that's now in my home to access the network. So we're either using one or two channels now to allow this little mini-home network to access the Internet. I'm currently the only one who has an account; I've bought an account from a commercial Internet service provider, InterNex*Tiara out in California. It's a \$30-a-month account, and I'm now able to dial to that account from either my wife's Windows machine or from my Mac, so it doesn't make any difference which machine I'm [working] off of — I can get to there from here.

So this is a very viable home installation. It is, in fact, the same model you'd use in a small school or a small office. It's going to build a small network, one ISDN device off that small network, and subject to how many IP addresses my service provider's willing to let me have and how many IP addresses this small terminal adapter will let me have — and some of them are limited in the number of addresses they can handle — I can allow all these people to share access on the bandwidth that I've bought up to the Internet.

Now, remember that in California, in the evening, I'm not paying any telephone charges here from this access because my service is less than 12 miles away from me, so I'm able to dial to my service and use it all evening for no telephone charges. I just have to watch the number of hours I'm up on the Net, because I get billed for overage, for going over a certain number of hours on the network; and once you let your kids find out how to do this they will exceed the number of hours you've bought. It's a law.

Okay. So, we're looking at putting things together here and where the costs go. Remember, I did not rip out my analog telephone; actually, I did not rip out the three of them, I just left them where they were because I didn't want to mess with that. I provided power, I provided an external NT-1, and that allows me to plug in and out the various devices as I'm working with them, because I don't always want to use the same device.

The next thing I'm thinking of adding to this network is a video conferencing mode for my house. You'll find video conferencing capabilities to be added to your computer coming down through the \$1500 barrier and headed for the \$500 price point, so it starts to make video conferencing a very viable alternative for working at home environments.

And then I have my external terminal adapter, and I think how much these things cost — I can go down to Fry's Electronics in Santa Clara and buy a Motorola *BitSURFR* for \$249. That's a dual B channel data ISDN terminal adapter. You thought, "Well gee, isn't that what a modem costs?" Well yeah, it turned out that it took the dynamics of enough people starting to buy ISDN in the quantities they did to make the manufacturers ask the chip manufacturers to build chips that did this cost-effectively, and so Motorola, Texas Instruments, Intel, AT&T Microelectronics, beat National Semi — these people are all now building ISDN chip solutions which are being built into products.

I think you'll find that ISDN devices will start to come out, function for function, at the same price as the equivalent modem products, but they'll run multiple channels and they'll run data five to ten times faster at that point. Now, everybody raise their hand who wants slower service. Okay. You just don't hear those complaints a lot. So everybody wants more CPU power, everybody wants more communication power and this is, in fact, the way that you can get them.

And what I'd like to say is that I can get the communications power that's on peoples' desks at Xerox PARC or Lawrence Livermore National Labs in California — I can get that at my home. The only difference is that I don't have the FDDI connection running past the desk that they have. That's a minor point. [But] for networking, I can do it.

So these are real, real street prices, if you will. Ninety-nine dollars to \$250 for the NT-1, and sometimes the NT-1 is built into the terminal adapter; \$200 to \$1200 for the terminal adapter; \$150 to whatever you want to pay for a little hub to go in your home; some Category 5 wiring; some good quality 8-pin connectors in your walls, and basically you can start to put together a home network, that — if you build it correctly, now — is going to last you for this application and will allow you to upgrade all the way up to 25 megabit ATM service some day — "asynchronous transfer mode" service, when some service provider decides they want to offer that to you on the network.

And how would you integrate that service? Well, you'd just plug that new thing in, and whether it was a cable modem providing [inaudible] of access or an ATM adapter providing bi-

directional access, you just plug it into the hub as another node on the network and have another gateway. You haven't thrown away anything in that network to add that new service. So it's my recommendation to you that you consider starting to do this in the home as you want to grow these services and sort of elevate your home to the same kind of connectivity that we've grown used to in business and educational institutions. You don't have to do this, however; you can, as I mentioned before, just run one device on a pair of wires, plug your computer into the back of it and just handle the one computer. This is a little more visionary approach if you want.

Where to check things out... I cannot recommend highly enough Dan Kegel's ISDN Home Page, and I'm going to show you that in just a second here. Your service providers you can get at bellcore.com. For individual users there's almost a better source of information at Intel's "Technical Help Desk," which is up on their Home Page under "technical assistance," and I can pull that up here in just a minute.

The Intel information will tell you what kind of ISDN service availability [there is] and what the costs are in your area. In fact, if you're interested in their ProShare service or their LAN access solutions, they will then facilitate an entire order for you for getting that service up and installed in your area. So I think there's a lot of Internet service providers who are starting to assist individuals in building these connections to their homes. There are also VARs, or "value-added resellers," who resale a lot of ISDN products and who will assist you in getting this to your home. Or you can go out to an electronic store and breadboard it together yourself.

And all of those can be very, very successful. You're going to be into different pricing schemes, [and with] your Internet service provider, each one seems to be different. Each telephone company in each state seems to have a different pricing philosophy on the installation and the ongoing charges for ISDN. In California, I guess I have it pretty good; it was \$37 to install the ISDN line, it's \$25.40 a month, and I don't have to pay for my phone calls within my calling area after 5:00 p.m., from 5:00 at night to 7:00 in the morning. So I can stay on my service provider in the evenings at no telephone cost to me [except for] the Internet service cost.

Now, [there are] some things you need to know. There are several types of switches you'll need to know, and you'll need to become network aware when you start ordering the stuff. What flavor switch is my service provider giving me? The AT&T or the NORTEL DMS 100 are the two most common. There's also Siemens' and Ericsson's. By the way, for those of you taking notes, this will be on CD-ROM, and it will also be up on my Home Page, at www.image2000.com.

Then you'll need to know what kind of line software the telephone company put in. Is it "national ISDN," [or what we call NI], which came out in about 1992 and is just now being deployed throughout the telephone networks? Or is it what we call "pre-nationalized ISDN," or custom software? You'll find variations, depending on which service providers are providing what kind of service. You need to know what kind of software the device you've just bought will handle; some of them will handle both NI and custom, and some of them will handle NI only.

There is another thing you must know. Do you have an [NC2B12] interface? I would expect the answer is yes, but if you're behind a PBX or some other ISDN key system and you're in a small business environment, you may have the T-4 wire interface directly. You can't plug something that needs the U interface into something has the T interface. You have to know your SPID. If you're behind any DMS switch or any nationalized ISDN service, you will need to know a SPID. It is the most commonly-made error in getting your ISDN working — incorrect SPID information. If you don't have the SPID... The SPID is what identifies your piece

of gear and your phone number and all your services to the public telephone network. If you don't have the SPID in correctly, the network doesn't know who you are and the switch cannot talk to you, so it is the number one thing.

The next most common thing [is that] you didn't match up the set of services you ordered. Remember, you can use voice services, data services and packet services, multiple directory numbers, all of these fun things — you didn't match what your equipment wanted to see out of the network with the order that you placed on the telephone company. Many of the telephone companies now have facilitated order desks that understand the stuff.

Be careful in ordering a home ISDN line, and in who you call. Don't necessarily call your residential service center to order an ISDN line. They may say something like, "Can you spell ISDN?" You know, "What is that?" The reason is that there are hundreds of people taking residential phone orders, and the telephone companies just have not had the opportunity to train all of them in what ISDN is.

Pacific Bell, for instance, has a single phone number, 1-800-4PBISDN, that'll get you to the right people who are specialists in ISDN. You tell them, "I want a home ISDN line and I'm planning on putting a Cisco 752 on the line." And they say, "Oh, we know what that is, and here's what you need." There's an excellent chance that line is going to go in perfectly the first time. If they don't have a service center like that — and some of this information you can get from Intel or from their Home Pages on the Web — then I'd say call the business office in your area for the telephone company and say, "I'm trying to install this ISDN digital phone line." Walk all the way through the process, get them to answer all the questions, then give them the address afterwards and they'll say, "I don't know where that is" and you say "It's my home, you know?" Don't tell them it's your home first. Get them to answer the questions for you; they will probably tell you exactly how to place the lines. But you need to do that through the business office.

And I don't mean to be devious here; I'm just saying that those business offices will have somebody with the expertise to handle an ISDN service request. You're going to pay different things in different parts of the country, so unless I could put up fifty variations here I couldn't answer all the questions on how much your service work will cost you. Depending on which service provider you dial to, you may get anything from a free connection at a university or in your corporate network to a dollar an hour or a \$10-an-hour range from a commercial Internet service provider.

Now what I want to do is shift gears here and show you some of these Home Page items and answer some questions at the same time. First, here is our Home Page in San Ramon. This is the one where we will post these three presentations we did today in GIF format so you can download the slides on a slide-by-slide basis. And it's got some information

The one bookmark that I highly recommend is Dan Kegel's ISDN page. The quickest way to find it is to do a *WebCrawler* search on Kegel and ISDN, and it will come right to the top of the list. This is the authoritative page on ISDN, and almost everything to do with ISDN is on this page. If I went down to the bottom here and took a look at the index, you can see all of the questions that are answered here on ISDN. It's got tutorial information, and even tells you where to get books.

By the way, the new book that's out is called *ISDN for Dummies*, and even those of us who have been in the business for ten years read it. You know, you always learn something. There are a number of good books, other good books at different technical levels. And then you get into the hardware, and if I was to look at the terminal adapter list from which you have to choose, in addition to the vendors out here on the floor, you're going to get a *Netscape* error.

So we turn to the trusty Mac and try again, where I don't have all the bookmarks, so I get to actually go through and do this. So I'll do... I think we managed to pull the Network down, that's great.

M: [inaudible]

Richard Brennan: Thank you. Now I've got a back slash. It's never my fingers' fault, it's always the keyboard's fault, have you noticed that? There's Dan's page. Let's take questions now. Any questions? Yes?

M: To get this little local area network architecture, like you have in your home, did the terminal adapter that you use, does it deal with [inaudible] between different service providers, that different computers often have?

Richard Brennan: Remember, it's a telephone model, so it is dialed up to a service provider. However, if all of the workstations on that little LAN have an IP address known to that service provider they can all be dynamically connected on that single connection. Now, yeah, they're all contending in terms of bandwidth, but that's handled in the TCP/IP protocol stack in the PPP connection. Now, it is conceivable that I could have, like an Ascend, one connection to my university and one connection to a commercial Internet provider, so I could be doing two remote connections at once and then, depending on where I was obtaining information from, I would actually have a crude connection between the two. So there's some interesting interactions there that are not always beneficial, and some people in that environment preferred filtered bridges to do corporate access to avoid that kind of inter-network routing problem. Does that answer your question?

M: Yes. Well, part of it. It's not going to be able to suspend long-term connection and/or request to connecting numbers, and a service provider comes in [inaudible] that's one of the advantages of ISDN, it's very quick.

Richard Brennan: Connect times.

M: Connect times.

Richard Brennan: Yeah, some of the board-level products will clearly be able to do that. And I think we're right at the verge of having some APIs between some of the access devices, and the computers for the access device would be controlled directly by the computer to be able to do some things like that. The protocols are there in the switches.

Things like data-call-hold are already in the switches, but I beg to ask, what is your communications software [going to] think when the switch goes data-call-hold? Most software is going to think the network just went south for the winter. It doesn't understand a suspended call in the way that his telephone-held call is; so we have to match those things up, and that's basically some API work that's currently underway at different levels and some different organizations, to make all that stuff come together so that yes, you could suspend this channel in order to connect up to that channel and go and retrieve something quickly, ditch that and go back to my suspended phone call. And remember, this could be a mixture of voice calls, fax calls, Internet access sessions, telecommuting sessions and distance learning sessions all in the same set of capabilities. Yes?

M: Yeah, I have two questions. First question for you is what's the physical wire connection for like a ATM going into the home? If you were to substitute the terminal adapters for ATM, is it...

Richard Brennan: I don't think anybody's standardized that. There is no residentially-standardized connection, and that's one of the minor issues. Since it takes about ten years for those standards to be built, it will be real interesting to see how that happens. I would suggest that most of the time it will be some kind of a connection that looks to deliver you what amounts to a 10BaseT or some connection that looks like that, as an industry standard connection directly out of an ATM connection.

But how it gets to your home — number one, it's not going to get to your home on the twisted pair that's in there now, because that pair won't serve higher than ISDN-type bands very effectively. And if you want to run ATM at 25 megs, that just — they're not going to throw that on the copper pair that's running around under the streets. That's what hybrid fiber-coaxial networks are all about, from fiber and coaxial cables, to get those kind of connections. And that is being done, and those services will be delivered over those networks before the end of the decade. Another question?

M: Yeah. Is the per-minute connect time charge a phenomenon exclusive to the New York area, or is that typical of ISDN charging structures?

Richard Brennan: It's typical of all business-grade telephone structures, and except [within a] few enlightened areas, ISDN is sort of then construed as a business type of service. I would put Pacific Bell in the enlightened arena, but even they knew that ISDN use during the day is most probably [going to] be used for telecommuting, so ISDN is "major great" during the day. Magically, during the evening when there's going to be on-line service access and Internet access by students and things like that, it's flat-rated; so they've tried to sort of tread the middle ground there and provide a service that met both requirements of recovering the billing minutes that you needed from commercial users but also providing inexpensive access for consumers.

I mentioned in the service provider session a little scheme called an "ISDN centrex," which gets around that by linking together all of the users in a single telephone wire center into a centrex, and has those ISDN lines then all be able to communicate without incurring message-unit charges. That may or may not be permissible under the tariffs filed in any given geographic area, and there may or may not be an ISP who is willing to set that up. Yes?

M: [inaudible]

Richard Brennan: Very commonly, yes. A lot of them have both a RJ jack and a 10BaseT and a 10Base2 on them. [There] are a lot of small TAs [that] have both. I just used a twisted pair because it was easier in the home, because it fit more the wiring scheme there. Questions? Yes?

M: Are you familiar with European ISDN?

Richard Brennan: A little bit. Euro2 is the EC standard, but there are variations for the French and German and UK networks.

M: So is that to say that a device that's U.S.-ready is not European-ready?

Richard Brennan: The [2B12] NT-1 is an American-only artifact. The T interface is very robustly standardized internationally, and in fact you can probably take a T interface ISDN device to more countries than you can any modem that you know of, and plug it directly into the network.

What you need is the software drivers for the D channel signaling protocol for those countries. And a lot of the vendors are real interested in selling internationally, because one of the great things about having an international protocol is you can build a global product. So many of those vendors do have the protocol stack for those other countries and yeah, you just request, say, "Hey, I need to run in Germany or France, and do you have the protocol stack that supports that?" You add that to your buying criteria and it will limit your choice of terminal adapters, but it does not close you out.

M: Do you know of any of these? Who should I look for?

Richard Brennan: Well, you can start with KNX, because they're from England and theirs works over here, so I think that would be a good one. Ascend certainly has made their products work internationally, and I think Cisco/CombiNet has too, and the rest of them I just haven't looked at closely enough to know. A voice telephone will be about the last thing; digital voice sets will be the last thing to be added to that list. They are the most difficult to communicate with the signaling protocols.

M: Is it practical to run a Web server on ISDN?

Richard Brennan: If you have — if you don't have usage billing, sure. It may not be as efficient as frame relay, but there are tradeoffs there as to how you want to run it. We were discussing, down here in the front, running a weekend-only Web service off of a Pacific Bell line. It would be a very viable idea, but you'd need to connect then to a service provider who could aggregate up your traffic. You would only be able to take a discreet number of directly dialed-in channel connections if you had to terminate the lines yourself.

[Tape change]

Richard Brennan: Primary connections just have not really been put together for home use there; it's almost always business grades of service. Their four-wire T-1 type connections, they are very difficult to get to places like homes without special conditioning on the lines. There are some other technologies being used to do that; I don't view that as a mainstream application.

Those of you who just have to have T-1 to set up your Web site will want to do that, but the mainstream population is probably not going to get there. Even in the broadband arena when bandwidth is more deliverable to home I don't see that as a primary delivery method, because it's just not the increment you can dial easily. We don't dial in T-1 increments. You know, I think there's a reasonable limit of about 384 kilobits; it's the best dialing increment. And we will get to there. It has to do with the ways that the networks are set up, the way the switch networks are set up. But for just a connection you could come down from a carrier to a PRI, if they would terminate to your home and if they could lease the facility to get there. That is possible. Yes?

W: I have ISDN and I was in the neat little stack of hardware instead of instructions. I didn't know what I was saved from. It seems like if you're trying to get to a million users you're going to have to make this simpler. Anybody working on that?

Richard Brennan: If anybody in here had to pay the salaries of the stack of people working on that, I think we'd all go bankrupt. I think some of us are trying to. There are literally roomfuls of people working on that in labs in many locations, and there are many efforts underway to simplify things and straighten some things out, to arrive at industry consensus around doing things in a better way.

What we want to get to is a plug-and-play scenario for ISDN, and we are quite a ways — it's still a hacker's dream, and you know, it's not where I would want to hand this to Aunt Millie and say, "Here's your Internet access device, just enter the IP address in MacTCP and wire your kitchen for a 10BaseT and go to it." It's not going to happen that way; we have to make it more simple, and that will come as these products go consumer-grade.

If you'll remember, heaven help us, what modem installations looked like in about 1968, then you'll kind of know where we are in terms of ISDN deployment. It really took a lot of doing to get modems to work right back then with high-speed modems, 2400 baud, so we're in that stage. But there's a lot of people working on it, people like Intel with Intel Blue — which is a simplified provisioning scheme, so you'll order an Intel Blue line and then it comes up as a standardized configuration that everybody can support. That's being supported in a lot of places. Up there.

M: All right. [Inaudible] no placing in ISDN?

Richard Brennan: Absolutely. If the network, if the other end is busy, if the network is congested... One of my favorite busy signals for ISDN calls is when you try and dial at 64 kilobits and you get the "all trunks busy" signal. And what it says is, "The trunk group of capacity zero is busy, because your switch is only networked at 56 kilobits." So people will keep repetitively trying to dial at 64 kilobits and say, "This isn't working, I can't dial." And you change their setup to dial at 56 and it goes right though.

You can get busy signals from any location that is full up to its capacity to terminate calls. In ISDN however, that is not quite as linear as you might think, because you can have held calls and you can have multiple calls on hold, so if I have four data calls on hold, am I busy or not?

M: But if your ISDN is only one ISDN circuit...

Richard Brennan: But how many channels do they have? I mean, yeah, you could say that's subject to engineering just like everything else. If they only have 284 channels available and 285 people are trying to dial, somebody is going to get a busy signal. That's subject to the same physical constraints as every other type of service. And that's what I'm saying; this kind of dial-up service adheres to the telephone rules of dialing up. You own the channel, you can get busy signals. It is not the same as a purely packet service, where you just get slower and slower and slower until it seems like it is busy.

M: Yeah, I was wondering, is the *Waverunner* the only ISDN [inaudible] with DSP base in it?

Richard Brennan: It may not be the only one but it's clearly the leader in there, and I don't know of...

M: Does that give you better interoperability, though, to buy something that's [inaudible]?

Richard Brennan: Well, theoretically, the advantage of the DSP is that if I wanted a new modem interoperability I could just download a new set of parameters to the DSP. The *GeoPort* is another example of a DSP-based modem, Apple *GeoPort*. So those are the kind of capabilities that those are building on. Most of the other products use stand-alone modem chips to do the same thing, just because they are a little easier to engineer in and they are cheap. Yes?

M: How easy or difficult is it for ISPs to accommodate the clients coming in on ISDN?

Richard Brennan: What you'd need to do is ponder your mixture of incoming analog dial-ins and incoming digital dial-ins and select a hub gateway device that accommodates that mix.

I think the good side of the story is that you can buy some devices that will, just as we discussed here. With either DSP or modem-based technology, a single device behind a digital primary connection can handle hundreds of people dialing in with a mixture of analog, voice-grade modem connections and digital connections. So you don't have to build a separate modem pool and a separate digital pool; you can build one thing that's digitally connected and handle people with a flexible boundary of modem dial-in and digital dial-ins. And the digital dial-in can either be single-channel or multiple-channel.

So you go talk to the [Viasens] and the CombiNet Ciscos of the world and Network Express and Gandalf and those folks and you know, ask them about their solutions for ISP-type applications. There's another question on the aisle here. Yes?

M: Once you go through the setup to get your ISDN working, it is more or less flaky than a modem-based [inaudible]?

Richard Brennan: In my experience, once you get an ISDN line setup correctly it's about like the Rock of Gibraltar. It is just bulletproof. I have been in an all-ISDN building for over five years and we've never had a system outage; we run all of our office automation on ISDN and we're now gatewaying ISDN to TCP/IP. The worst problem we've had is an occasional wiring problem that causes a flaky set here and there, but we have not had one second of system downtime on the ISDN.

I challenge people with PBXs and LANs to make that same statement over five years. Occasionally we've had network congestion where calls couldn't get through from this part of the network to the AT&T network, because we're behind Pacific Bell Centrex for about three hundred lines. We've occasionally had network congestion problems but everything inside the building — all the networking, voice data — everything was working inside, and that's been over five years now. Telecommunications downtime is measured in the minutes and thirty-year periods. You know, it's little different standards that the stuff is built to. Yes?

M: What about connecting to your ISP, like [inaudible] 45, 60 minutes — whatever it is to the phone lines?

Richard Brennan: That's how you select ISPs, by the reputation for service, and it's not just — I think a lot of that maybe you're getting a quote "dirty analog line," so fundamentally if the ISDN line can establish a connection they tend to go up and stay up much more readily than analog lines.

A little anecdote from my building: I was doing a video conferencing setup inside the centrex — but remember, in my building my centrex line from my video room goes from my room down the street to Pacific Bell's central office and back to the laboratory — and I dialed up a 384 kilobit video call, which is a synchronous data call much like a LAN access at 384 would be. It was doing the “send” IMUX, and I dialed it up on Friday; and I forgot to tear the call down on Friday and I came back on Monday and the call was still up at 384 kilobits. Unfortunately I'd been away in the middle of the week, so it was a nine-day call at 384 kilobits.

I defy anybody to sustain any kind of a data call for nine days on any kind of modem capability and still have data synchronization in your application. It just can't be done. By the way, it was a no-cost call because it was intra-centrex. If it had been to Hong Kong I probably would have heard about it in my — in my previous job, you know. I'm a short-timer, I've only been there twenty-five years.

Okay. Any other questions? Last person out has to buy the cocktails, is that the rule here? Yes?

M: Where is the [inaudible]?

Richard Brennan: Well there are three AT&Ts, each of whom fit into the scheme. There's AT&T as a service company, and I cannot speak for them as to what their strategies are in ISDN. There's AT&T as an equipment company — we're committed to ISDN standards in providing a broad range of products that we make in our factories, and we have relationships with other vendors to provide for ISDN.

You just saw the announcement with [GBCS] and Ascend, and we're also building the hybrid fiber-coaxial network for three million homes for Pacific Bell in Northern California. So imagine a 750 megahertz connection capable of supporting, ultimately, things like symmetrical ATM and personal video conferencing and multiple ISDN lines and interactive television and cable television all on one connection to your home. That's the kind of technologies we're putting together with our service partners, and that includes all the LECs, the independents, inter-exchange carriers, and anybody else who likes to buy technology. So I think that's a very large role.

Thank you for your participation. After three sessions, I think my voice has just about had it, but if you care to come down here I'll continue to answer questions while I pack this up. Thanks again.

COMMERCE WEB LEARNING FROM COMMERCE TO COMMUNICATION TO COLLABORATION

SPEAKERS

Michael Palmer

Director, Digital Media and User Interface Lab Center for Advanced Technologies, American Management Systems, Inc.

Robert A. Duffy

Managing Director, Strategic Communications

Robert A. Duffy: I have a small consulting firm specializing in communications, which means everything from ghostwriting to strategic analysis of communication needs for large organizations. What we do is advise corporations on how to reach specific audiences and supply the content, in effect, for reaching them, multimedia content included.

I work for organizations like American Management Systems, which is Mike's company, the Corporation for Public Broadcasting, The World Bank, The International Finance Corporation and several other, but mostly large organizations. Again, our specialty is communication of substantive material, and we're moving rapidly into the area of knowledge management, knowledge infrastructures in organizations. That's what our session today is really all about.

Michael Palmer: Thank you, Bob. I want to do that because Bob and I are going to conduct a very interactive kind of session today, and that applies both between ourselves and with you, the audience. So, we do have a rather large group, but I think it's a sort of nicely arranged one that we'll be able to manage if anyone wants to interject, offer some of your expertise or knowledge. I think that everyone in the group would appreciate that, although Bob and I certainly have plenty of information that we can spit at you, if that's what you prefer. But I think, in general, it's a more interesting session — it has more value for us — if we can interact a little bit. I think that's a key point.

Although we've organized it, more or less, along the format of a tutorial, it's not meant to be a tutorial. We want to hear from you. We want you to kind of redirect us if you have ideas. Some of the sites we visit will be interesting, but you may be able to suggest some others that are equally or more interesting. The thought that we're presenting here are not bulletproof by any means, so we welcome questions at any point along the line. Please feel free to jump in at any point, really.

If there's one thing any of in the industry has learned it's that change is ever-accelerating at a very rapid pace. I think that people in this room, people at the conference this week, are individuals that will be making many of those changes. So, it's kind of up to us to foster that collaborative kind of environment and see where we can go with it. That's one other point. We're talking a lot about communities of interest in this session today; this is a wonderful community of interest right here in this very session, and we hope we'll be able to do some of the same collaborative approaches that we talk about in our prepared material.

Robert A. Duffy: How many of you saw some of the statistics that were on the CNN sound byte this morning? Anybody happen to catch that? A couple of you news junkies out there. One of the latest surveys of which we know — there are several, probably a thousand by now — pegs the on-line contentions, or audience, at 25 million people worldwide. Of those, it's estimated that 66% are male and the remaining 34% are female. The age group that is most predominant is 16-34; that makes up 56% of this audience.

But the astounding [thing] to me was that in spite of a lack of standard, secure transaction capabilities for buying and selling goods on the Internet through the WorldWide Web, perhaps 2.5 million of that group, 10%, had already purchased sometimes multiple goods or services through the Internet. Just in the room, how many of you have purchased something purely on the Internet — completed the whole transaction? Looks like a lot more than 10% to me. But then again, we are a kind of leading audience in this arena, and many of us are enjoying the benefits of knowledge of this new area.

Well, today in our session we're going to talk about a number of things, beginning with commerce, the idea of point-of-sale, perhaps exchange of information, and good and services. We'll talk more about communication as we really shift away from the commerce arena, kind of broadening the definition of commerce, looking at this from more of a business perspective — ways that organizations and enterprises can leverage their intellectual assets. We'll talk a little bit at the end about collaboration, things like internal webs, ways that organizations are benefiting from an increased range and scope of communication between their key stockholders and employees.

Michael Palmer: If I may interject something... We'll take commerce as our starting point and work outward in the areas where commerce begins to depend, where point-of-sale specifically begins to depend on the exchange of information to work. And, of course, that starts with pre-sale support and post-sale support.

But before you know it, that body of information begins to expand and cover other elements such as institutional identity. The corporation that's selling these goods and services tells you who it is, what its values are, etcetera, and you can see that there's an expanding universe of information that surrounds this commercial intent at point-of-sale. That ultimately becomes a learning process for the organization. As they gather information to put out on the Web, they begin to learn more about themselves. They begin to collaborate more and they begin to see their activities in a collaborative context, both within their organization and externally with potential allies.

So as a starting point and as we begin to explore commerce, we ask ourselves, "Well, what is commerce?" Clearly, it's buying and selling — an exchange, perhaps, of monetary value, an exchange perhaps of goods in kind, but still an exchange of some value for a product, service or good. Is that all that commerce is?

Well, our premise is no, absolutely not. In fact, that form of mercenary transaction, that kind of commerce, is really a very small part of the equation. And in fact, the social commerce or the flow of information, that form of commerce is a far more important dimension of the communication capabilities and opportunities afforded by the Internet and other external networks.

Look at the background information. Who would have thought that by presenting information about your organization or firm in a very "PR fluff" kind of aspect — just rip it right out of your annual report — who would have thought that that would be an important part of a buying decision? We believe it is and that we need to work to delve deeper into that arena. The idea of the information flow is an essential component of commerce, and it carries with it some understandable dimensions that need to be explored — namely, who your audiences are.

So, if you come at this from more of a marketing communications perspective, perhaps you realize that you need to identify the audiences that your organization depends on — key stockholders, people who influence the activities of your business and influence your reputation, perhaps a whole [inaudible] who really serve as the underpinnings of your identity out there in the world as an organization. And if we look — and we will explore a few sites — we'll see that this form of social commerce, this flow of information, is really already our

mainstay on the Internet and on the Web, perhaps far more so than the pure mercenary form of commerce where I can buy a tennis racket or buy a pair of sunglasses or order a pizza.

Given the right circumstances they're all incredibly useful, but perhaps not the most compelling or important or valuable way of utilizing the Internet. So, does it make sense to start with commerce? Well, point-of-sale is certainly intriguing, but again, in a nickel-and-dime sort of way. What we're going to do today is really look at that as sort of our starting point. It's a good lens.

We're going to take a look at what begins as a very simple element and then build that into a strategic vision of the communication and collaboration infrastructure that these public and private networks represent.

Robert A. Duffy: This is kind of a backwards way of approaching it, but point-of-sale commerce does represent kind of an ideal lens look at the whole expanding universe of information on the Web. It gives us an albeit artificial, but very useful point of view to see how information and communication move out from that commercial kernel, that point-of-sale issue. But again, all of this information — the information dimension of the Web — is far more extensive today than the point-of-sale dimension. So it is still a little bit artificial. We've built a model here that you'll see in a moment evolves.

Michael Palmer: So what are some of our keywords for today's discussion? Well, commerce, clearly, which by now you feel like we've really beat into the ground. Information has a lot of meanings, but has a lot of value. Infrastructure, the underpinnings, the ways that we can conduct activities, support our business processes and communicate with other stockholders and audiences.

Knowledge, some might say, is different than information. I certainly do. There's a distinction to be made which we'll elaborate on further. But in general, knowledge is something that may be captured or stored in a variety of resources; it might be on-line as databases and digital information in your computer on the Internet, but it's also right here, in the production systems your firms have set up. It's in the relationships that you've built with outside entities and perhaps even with internal constituencies. So knowledge is a much broader, more encompassing form of information.

And collaboration, team work, common cause. How many of you are surprised to think about the Internet as a team work or collaborative tool? Anyone? I hope not. Good. Well, what is that all about? Hey, it's within your organization; it's training; it's being able to manage projects. Perhaps it's being able to conduct business from a virtual organization. Why bring 50 people across the country to work on specific products or services or projects when you can have them collaborate through these networks in a way that keeps them at home? So our next segment here is going to focus, again, on commerce.

That was our introduction overview to the concepts. I do want to take a process check right now; we have built in a fifteen minute break about halfway through the session. With a larger group like this, it's often difficult for people to be reassembled and get started again, so I'm going to put the question to the audience. Would you prefer to have a specific break and kind of hang in until that break, or just keep it open and if you have a need to go to the facilities or the telephone or something, just take off and do that? So, anyone who wants to have a break with a set time, hands up. Okay. Then we'll just keep rolling right along then.

Robert A. Duffy: You may be more inclined to do so as we proceed. Please let us know.

Michael Palmer: Well, here's a kind of beginning model, commerce model #1. This is a relatively

simple chart, but it has a great deal of information embedded in it. If you look to the top half of this chart — I guess I could move the pointer around up here — this really represents the organization, although it has gotten a bit off the side of the screen. So the top half is your organizations, your companies, your non-profit organizations, your research institutes, your universities; the bottom half, well, represents the marketplace. So this is kind of the external world at large.

And the elements that we see in the middle here are really the interfaces through which your organization will communicate with the external world. We have a fairly large one here in the middle. Of course, that's the topic, primarily, of this discussion and this week's conference — the Internet and variants thereof. On the sides we have our traditional channels, and these are the ways that people are conducting business today: telephones, faxes, FedEx, mail, human beings — imagine that, human beings — telephone support, and sales staff.

The point in including organizational information resources — of course most of you, I guess, are information professionals — is to indicate how important that is in the whole structure of running the operations of an enterprise, business or nonprofit, and the real-world operations obviously draw on those organizational information resources.

At the same time, this network infrastructure — or Web infrastructure, if you will — is also a point of interface with the real-world operations.

Robert A. Duffy: If you look today at what most of the interest has been about, there's sort of a green line; it's even visible. Most of the commerce on the WorldWide Web, for instance, has been really focused on this kind of fulfillment, and some of the activities related to ordering and processing those orders. There's a whole range of other activities and we believe the internal and external webs are going to be very efficient in supporting in organizations.

This diagram will come back to us again in several forms as we expand on it and really build into a more complete model of commerce and collaboration and communication.

Michael Palmer: Does anyone need clarification on this model as it exists, or [are there] any questions about it? It will change; it will evolve as we go on. That's the simple model of commerce using point-of-sale as the focus.

Robert A. Duffy: One of the early examples of this form of commerce on the Internet was, of course, PC Flowers and Gifts. In fact, I know that Bill Tobin is going to be presenting a session this week, and I believe he's been very successful at that. I think we're going to go ahead and take a quick, live look. As we're doing this, if anyone has some thoughts about other resources on the Internet, other URLs you might have in mind that are some of your favorite commerce sites where you're really looking at just buying and selling goods, we can certainly set up those and take a quick peek there as well.

Why don't we go ahead and take a spin, see what we've got here? Anybody need a teddy bear for their wife or sweetheart? [You can purchase it on-line at] Bears by Russ. Here's Byron, the bear from the past. Look at that, a little tag that helps us become more interested in this particular bear. It's eighteen inches sitting. Let's see a view of that, I'm interested. I think that this might make up for me being away for the week. Look at that; mmm, ooh, ahh.

Minor issues aside, it is kind of unique to be able to browse through this kind of information 24 hours a day, seven days a week. I wonder if we can go ahead and order, given that we've identified a product that we're interested in?

M: A point of information: what speed connection are you running in?

Michael Palmer: I believe this is a T-1. I know that there is a local Ethernet set up in the building, but I'd have to direct that question to some of the Internet World organizing staff. Okay, so look. We've got a search engine here. Oh, okay. Well, that's kind of an interesting value point, isn't it? [They have provided] a way to suggest some appropriate gifts, given a special date or event. Bob, did you want to expand any on...

Robert A. Duffy: No.

Michael Palmer: Were there any other mercenary commerce sites out there that you want to take a look at? Pizza Hut, Sunglasses Hut?

M: A question on that one. There's a thing up there. What's an SSL [inaudible] browser? How does anybody buying a teddy bear know what that is?

Michael Palmer: [That's a] fantastic point.

M: And a second question for this site and other sites: what's the current model for actually fulfilling the transaction? The secureness of credit cards; is that something you're going to get into here?

Michael Palmer: Absolutely, yes. What are the hold ups? Why hasn't this form of commerce exploded, totally supplanting the mail-order catalog business, perhaps [even making the] Home Shopping channel go away? Well, what is the hold up? Is it secure transactions, is that lacking? Do people care? Do people know, in general, what that's about?

We do, perhaps, in this room. [We are aware of] the ability to transmit your important financial data — perhaps a credit card number — and order information to a vendor without fear of it being intercepted and perhaps surreptitiously utilized. The ubiquitous access question is interesting. Are there enough people who have access to this forum, this communication channel, to be able to actually act out the buying impulse?

We actually think it's somewhat those, but perhaps more importantly, it is simply customer behavior. This is a social issue. This is a change management kind of issue. I mean, we in this room are sort of early adopters. We're leading-edge people that are seeing value in a really revolutionary way of communicating and interacting, doing business, buying things and selling things.

But by and large, we're a very small percentage of the buying public. So perhaps secure transactions have a concern. SSL, Secure Socket Layer, is just one of several standards that is battling in the marketplace today. I know there are many other sessions that focus principally on these issues, so we're not going to delve into them too deeply.

Is there more that you'd like to expand on with the Secure Socket Layer question? I know that you hit a very hot button for me. I'm a user interface specialist in my other spare time, and the question was, "What's an SSL and does anybody care?" I think not. This is a code. It's jargon. It's something that really has absolutely no business being in that interface, so maybe there's some improvement we can make on these interfaces to make them more user friendly, to make them more better match the audience that we're trying to communicate with. That's very important. We'll pick that thread up again throughout today's presentation — matching your form, style and content to your intended audience.

Robert A. Duffy: When we speak about these issues of secure transactions, is everyone up to speed on that? I know there are a good number of Web neophytes present at Internet World.

Do you need some background on that?

M: I have a question. Where should SSL go, or secure transaction? [Where should] that kind of concept go if it's not in the user interface level? So you're saying people coding the [inaudible] shouldn't worry about that. Where should it go?

Michael Palmer: The question is, where should those issues appear? Our premise is that they don't need to appear in the interface because the audience doesn't know what they are and couldn't care less what they are. They're a benchmark task.

What they're trying to accomplish is to purchase a good, product or service through the Internet. So SSL, and any of the other secure transaction mechanisms and standards are really background, hidden from view. The user should never know about them, see them, hear them, feel them, touch them or realize they're even happening. It's part of the magic that makes this whole communication channel work. Every time we have that kind of element in an interface, it adds complexity and scares people and can have the detriment of turning away perhaps a segment of this buying audience that in fact we may be trying to reach.

I see another hand in the back.

W: [inaudible] your phone conversation will be eavesdropped on when confidential information is being given out. I honestly believe that the average customer has no awareness of those issues. They don't realize how their privacy can be compromised.

Michael Palmer: Okay. So there's an issue of, again, not misleading potential customers and drawing them into an environment where they could be harmed in some way. So where would that information go? Well, perhaps not to be presented as an SSL but to be presented as a means of securing your important data or information or transaction from prying eyes.

Now, there's some sense — and I'm going to be a contrary here for a moment — that I have understood the security issue of purchasing small ticket items such as flowers and gifts and things under ten thousand dollars, say, on credit cards. There's a sense that really the concerns over security and "Gosh, someone can tap in and steal my credit card number," are grossly over-exaggerated, perhaps even manufactured by organizations and entities that may benefit from scaring people about the security issues.

For instance, how hard is it — to impress some technical people in the room — how hard is it to tap into a TCP/IP data stream on the Internet? What do you need to have? You need some packet sniffers and you've got to have an access port to get into a network center somewhere and feed off the routers and the bridges and whatnot. You have to have a very high level of technical sophistication to do that. How hard is it, on the other hand, to pull your van up to the local telephone pedestal outside a mail-order house and record a week's worth of telephone conversations where people are offering their credit card numbers day in and day out? I would argue that that's a far better understood technology and a heck of a lot easier for people to tap into.

Credit card slips, there you go. Listen, I had a credit card stolen. We didn't realize it was time for the new one to come in the mail, and of course we didn't realize it hadn't arrived until three months later. We had a maxed-out credit card with charges all over the country.

Someone went on a real fun buying spree. Was I liable? No, because in our agreements with all of our credit card issuers and providers we're protected at a fifty dollar level — at the most — from unauthorized charges. Those are very clearly defined as those for which we have not signed and have not authorized through a physical means.

W: The point that I'm trying to make is that [inaudible] is basically provided by regulations in the banking industry. You'd have to check with the consumer. But there is no such place to protect the consumer on the Internet.

Michael Palmer: But if you use a credit card you are protected.

W: [Inaudible] possibly is one of the avenues for doing that. But if you started to look at other avenues, bank accounts and things like that on the Internet, there are other issues that consumers are not going to be protected from in that environment.

Michael Palmer: Right. What if you could make [an] electronic fund transfer?

W: With an ATM card, you're protected by banking rules and regulations.

Michael Palmer: So what do we think? Does this sound like an issue that is an important one for people to follow up on and perhaps work to have similar restrictions, regulations and legislation enacted to protect these kinds of transactions? Anybody want to offer a thought?

Robert A. Duffy: The gentleman up there.

M: The point is, you want to [inaudible] You need to know that [inaudible] are there. People are reading about it in the media. The media is also coming out with stories about the Internet, and a lot of security experts would argue that the same laws we have protecting telephone conversations and credit card transactions are easily applicable to Internet transactions.

Michael Palmer: Okay.

Robert A. Duffy: That does go to the issue of customer behavior and customer trepidation about using the Net. In my survey of the media coverage of this issue the press are, by and large, alarmists. In fact, they don't press the points that you suggest, true or otherwise. I'd like to see more coverage in the press to indicate that there are greater levels of security on the Net today than the alarmists' voices would have us believe. But until that happens, the public reaction across the board is going to be generally shy.

M: [Inaudible] *USA Today* poll today, and the newspaper said that 52% of the population of the U.S. believe that the computer security will be better or much more improved than it is today in the year 2000.

Michael Palmer: These are good. And perhaps by that time the trepidation level will drop, and we'll see more than 10% of the available on-line community engaging in transactional commerce. We're spending a great deal of time talking about some of the issues that may be roadblocks to a widespread adoption of these kinds of commercial transactions on the Internet. That would — if we continue to spend that time — imply that we believe that mode of transaction was the most important mode there is on the Internet. In fact, our premise today is that it is not; it is a very small portion of the value to be had through this revolutionary communication medium, and we're going to move on to more collaborative and perhaps communication-centered processes.

So here's our commerce model #2, which you will see is largely the same as commerce model #1. Down here on the bottom you see we've added potential customers in addition to

customers. This would be an audience of people who don't know anything about our organization, our firm, our products, our services, our stance or our research, and would like to know more because they perhaps want to — what? Buy from us? No, maybe not. Maybe they want to collaborate with us. Maybe they want to build a relationship with us.

Up in the top we see that the point-of-sale has shrunk. Obviously, we're again moving away from that concept of mercenary commerce, this being the overriding reason for being on the Internet. I've added some elements here to the real-world operations, namely pre-sale support. How about if we can communicate our catalogs, our data sheets, our specifications? We may not result in a transaction happening on the Internet, but does that matter? I think not.

We may instead get requests for demonstrations or perhaps inquiry response. Now, you'll notice that these sort of aqua panels on the right and left — post-sale support and pre-sale support — actually transcend the network infrastructure, which would imply a communication with the audience through the Internet or through a network of some kind. But they also exist in real-world operations. Today, in most organizations, these processes are being carried out and conducted in the real-world, utilizing traditional channels such as people on phones, people with faxes, FedEx, paper documents and contracts.

The help desk and follow-up is kind of unique. Actually, many of these we could probably put into a time dimension and look at how different types of organizations will adopt these particular types of processes as network-based processes, and we'd see that obviously the computer industry is going to be the first.

In fact, how many of you are from a computer product firm — software or hardware — in the audience today? Okay, well over half. Of you, how many of your firms are already using the network channel to provide installation instructions, technical support, or maybe just e-mail for help desk type issues? Keep them up for a second. So about half of the individuals of the computer products and services firms. Of the half that are not doing that yet, are you planning to? I don't see any hands. I hope so; I can't imagine a better marriage between an available audience and the need for information. Again, perhaps it's not transactional commerce to buy the product, but about using the network channel to get product upgrades.

I was astounded to see that the Sun Service division was saving \$1.3 million a month in shipping and personnel costs related to preparing user software upgrades because they are now distributing those over the Internet, as opposed to mailing out physical tapes, cartridges, floppies, whatever. They're a big company, but that's still a big number even for a big company. There are a lot of other processes that dovetail very nicely with the current capabilities — security issues aside — and with the existing Internet.

Robert A. Duffy: Is everyone with us in terms of how this model has evolved a little bit? It's expanding outward from that point-of-sale function to include corollary information that has to flow to customers. But not just customers; potential customers as well. So there's a new wrinkle here, the notion of bringing customers on board, of selling them in effect. That transaction is an information transaction. It's a relationship, and these are words that are going to recur in our discussion.

Michael Palmer: So if you're going to clinch the sale — again, we are still in the commerce section, we're talking about selling a product or service — we need to describe what we're offering. We've already seen this. What do product descriptions plus pictures plus ordering information equate to in the real world? Catalogs. We already looked at one, PC Flowers and Gifts, an on-line catalog.

Now we're going to take a look at another site, L.L. Bean.

Robert A. Duffy: Of course, in the mail order channel, L.L. Bean is the granddaddy of the catalog channels. Here is its Net presence, and we've already drilled down into the interface a little bit to save time.

If you click on "Apparel and Accessories," you're presented with another list of a panoply of possible choices. We'll do "Fleece Jackets," and you'll see this is remarkably like a print catalog presentation. What's up with that? I thought the Net was the land of icons and image maps and sparse words. Suddenly we're back in the universe of textural coverage. That's one step. If you try to order from L.L. Bean you get an order form where they say, a bit disingenuously, "We will not accept orders via e-mail due to our concerns about the security of your information," as if everyone out there, speaking of customer behavior, wants to order by e-mail.

But L.L. Bean is saying, "No, no. Not secure yet. Let's do it through traditional channels for a while until we can protect your interests." Well, of course, that's a marketing pose in a way, and they're making the best of a bad customer attitude situation here. Mike, did you want to comment on this?

Michael Palmer: Well, I believe there are some other features. There's a park search that exists. Let's touch on that very briefly. One of the core values of the Internet, and the WorldWide Web of course, is the free exchange availability and provision of information as a service. L.L. Bean is being a responsible network citizen in that sense by offering the park search feature.

Robert A. Duffy: Let's defer that for just a second because there's one other feature I think that fits in before that, and that's the background information on the company. The [park search] is something we're going to look at in a moment, but we come from the realm of the catalog to the realm of institutional identity. They've got this Web server; they have the bandwidth to satisfy customer inquiries; so why not talk about the nature of the company, the history of the company?

We're moving out very rapidly from a notion of sales support to a broader concept of that relationship with the customer — supplying identity. The next step of course is, as most of you know, to build prestige and convince the customer of your value in their particular community, in their particular universe. That, I think, is where the lifestyle tie into the park search service comes in.

Michael Palmer: The park search service is not only, as Bob pointed out, in keeping with the core values of the Web. This free provision of information is also a hook to an interest group, a special interest community — perhaps individuals who enjoy recreational activities. They go to national parks to pursue many of these activities, and here's a way that L.L. Bean can tie into some lifestyle mechanisms to keep people coming back, to keep people interested in building a relationship with L.L. Bean. Customers are not just doing a quick sale and getting a sweater, but building a relationship.

Robert A. Duffy: I think I'm in a loop here.

Michael Palmer: Did we lock up?

Robert A. Duffy: Yeah.

Michael Palmer: Well, suffice it to say, for those of you who have not explored this, it's a very nice compilation of state park information which is accessible through all of the different

keywords pertaining to activities like kayaking, camping, tennis, hiking, boating and canoeing. It is also accessible through geographic location. I want to go ahead and go back and maybe you can reset that.

So the issue of identity is important because people, organizations — any external entity who may want to develop a relationship with you, whether it's a buy/sell or collaborative venture, whatever — are going to want the context to understand who your organization is, what you do, and how that relates to the marketplace at large. What are your activities, products and services, your core competencies, the things that you're particularly good at — special things that set up apart from the rest of the world?

Look at this. "Mission and Values". There's your annual report; but those are important elements of identity, their history — and perhaps most importantly — their view of the future. Now, there's been a lot of concern in my industry — I'm in management consulting and systems integration — a lot of concern in my firm in particular, with presenting information about our view of the future, because this is kind of like saying, "Well, gee, if we give it away then everybody's going to know, and our competitors are just going to get right in and copy it and see it and use it."

These are issues that are being navigated in organizations everywhere. Today is anyone involved in selection of content to present through these Internet channels? I see quite a few hands. Would anybody like to offer comments or maybe have a similar war story in terms of knowing you'd like to present information, but having restrictions placed on that because of confidentiality concerns or worries about competitors picking that information up?

If it hasn't come up, it will soon, so be prepared for that. But every one of these issues that builds an image, an identity — a feeling of warm fuzzies, if you will — about the organization that I may be engaging in a relationship with, these are all crucial elements and play a very strong part and role in impressing an organization to join or do business with another organization.

So Web commerce seems to be more about communication than it is about point-of-sale transactions. Succeeding and building image and identity is more about how you communicate, perhaps more than what you communicate. They're very intertwined and very important. There's really a marketing communications viewpoint that's very important to bring and superimpose on some of the existing kind of way-cool Internet Web surfer issues. We have a question in front.

M: [inaudible] example we just saw was a great example of cutting the communication line. I'm sold on the company. I'm sold on the product. I want to buy the boots. What do I have to do? I have to turn off my computer, turn off my modem and pick up the telephone to order them. They've just cut the communications off.

Michael Palmer: Well, let me turn the question out. I admit, I experienced the same frustration, but let's go on the other shoes and say, "I've just invested 15 minutes in learning about the product and perhaps selecting it, comparing it to the competitor's products. Now I want to buy it." It's a roadblock, but is it a concrete roadblock? Maybe not. Maybe it's a little barrier I can walk around.

M: I guess [inaudible] shopping through my catalog for an 800 number instead of [inaudible].

Michael Palmer: Right, and you know they'd rather not do that. I think they'd rather not cut the communications line. They simply have to because of their perception of the public perception. This gentleman over here had a point.

M: If you're on the Internet, I think browsing around [inaudible], but most of the time you get the catalog. It's much easier to do it that way, with the catalog in front. The other thing I noticed here too is the catalog that gets delivered to your door is far more [inaudible] on the computer screen. It's high resolution. It's quicker to access. You might find other things as you're going around.

Michael Palmer: That's an interesting observation. It really leads into a discussion about the premises that the printed catalogs, the traditional means of communicating with the catalog, is in essence, easier to use. It's higher resolution, it has a broader bandwidth of information, it's more comfortable, and perhaps a better mechanism compared to the on-line services.

We all know that there are a lot of technical issues involved. Everyone does the best they can in presenting information through a narrowly defined standard, and there are ways of breaking out of those boxes. We'll soon have bandwidth on demand and gigabyte per second networks to our wristwatch, but it's going to take time. Right now, the catalog in print is a very different form of communication and can be leveraged because of its advantages in certain ways. Now, let's think, let's do a thought experiment. What about leveraging the on-line catalog in a way that offers value to the consumer that you can't get from a catalog?

Specifically, I'm thinking about a collaborative venture where, perhaps L.L. Bean teams up with — my God — their competitors, selling other sporting products and other goods related to their markets, so that the consumer has a one-stop point of access to come in and do perhaps a search of 30 catalogs worth of products and goods all at once. I certainly get frustrated. How many catalogs do you get a day? The pile of catalogs actually exceeds — for me — the pile of trade journals that come in.

Robert A. Duffy: It's the print catalog we're talking about. This may be a generational fixation, believe me, but tactile satisfaction. How much better does it feel to have a book, a magazine, a sumptuously-printed product in your hands than to be on-line? Again, this may be more characteristic of 35+ individuals than 20-somethings. Your laptop doesn't fall on the floor when you fall asleep.

Michael Palmer: And how many of you use your laptop to shield your eyes from the sun when you're walking around the beach? So there is a great difference between the different media being used to communicate, and perhaps this is a user interface issue because today's screens, today's mouse/windows interface, is limiting. It's very old and it's served its time, but we're ready for a more pervasive, less intrusive kind of interface, which we already have in many of these printed materials. The woman in front.

W: I think what we're looking at is a very big phenomena because I think that print catalogs and on-line catalogs are going to be competitive in many ways. What's going on in the direct marketing industry is the cost of paper, the [inaudible] environment, the people are getting sick of getting this in terms of throwing out paper and recycling. You've also got the increasing cost of postage, which is causing a lot of catalogs to go out of business.

And the other thing that on-line catalogs are the up-to-date [inaudible] because as the postage and paper go up in price, they're not going to be able to send out those updated.

Michael Palmer: So despite the limitations of the on-line presentation, perhaps there are other value points that we can leverage: timeliness of information, being able to do spur-of-the-moment sales. How about doing real, personalized selling? What about gathering information

about your potential customers so that you can suggest cross-sales, so that you can really target a range of products that will be very in line with someone's interest? It's hard to do that with catalogs because you'd have to print 25 different versions of your catalog.

W: [inaudible]

Michael Palmer: What's your cycle time on printing that media? You're right.

W: [inaudible]

Michael Palmer: The gentleman.

M: We were talking about L.L. Bean's channel of communication, and I noticed that on the L.L. Bean screen there were two options underneath, by telephone or by computer with word processor.

Michael Palmer: The thinking there was one of them was an *Acrobat* file, a portable document format file which you cannot edit, but you can certainly download and print a very precise representation of the order form that you would find in the catalog. The idea was that you would print that out, fill it out by hand and perhaps fax it or mail it back.

The form for using a word processor was like a word document that you could actually edit the text in. So you would put and type your own order in, which I think is a great value to L.L. Bean — more so than to the consumer. I don't know about you, but I probably find it faster just to scribble down the numbers and send it off than I would to get into my word processor, type it out, save it and then e-mail it. Those are barriers, definitely barriers.

W: [inaudible]

Robert A. Duffy: In other words, even though there must be other ways to add value to the community by doing that.

Michael Palmer: Audience, what do you think? Does L.L. Bean miss the point? They're just regurgitating their catalog. They haven't taken advantage perhaps of some of the new functionality and capabilities. Your order history —you know that company is storing it. How about if they let you see it, too?

M: [inaudible]

Michael Palmer: More in-depth information. Can everyone hear what this gentleman is suggesting? More in-depth information is available on-line than perhaps you could ever hope to print in a catalog because you'd have a ten thousand page catalog.

So perhaps the catalog is the teaser that draws you in to interest, but on-line you have a much broader range, a more complete universe of information about not only those products, but also the company that I want to enter this relationship with.

M: They don't want to take your order on-line. I'm actually turned off by this company.

Michael Palmer: That's the second comment. You guys are all up in front. Anybody in back have that feeling? A couple of people.

M: [inaudible]

Michael Palmer: Fantastic. So we use the on-line communication channel to build a group of interest. "I want to be on your hiking list so I can learn about new products and services in that arena."

Robert A. Duffy: And you're beginning to move into the realm of a collaborative mode of customer relationship at the same time you're extracting information from that customer, building a profile on that individual and creating a kind of platform for "customer intimacy," as it's called. Some of the points that Mike raised, where you know that customer's buying habits — and this may be a little intrusive on privacy issues — you know that customer's buying habits when he or she comes on to make an order. Then you suggest related products based on his buying history.

Michael Palmer: So building that sense of belonging in the special interest community that perhaps L.L. Bean could create would be a key factor in convincing individuals to enter into a relationship on a long term basis with that organization. Urgent question.

W: [inaudible]

Michael Palmer: Interesting. Kind of like Levi's system where you can have a custom-fitted pair of jeans ordered. There's actually a couple of laser-ranging systems that let you walk into a fitting room, and the laser beam shoots around you to get important measurements. The next day, by express mail, your perfectly fitted pair of Levis comes to you. So customization of product is another way of enticing people.

W: I want you talk about [inaudible].

Michael Palmer: The two-way communication.

W: Yeah, the exchanging of the information.

Robert A. Duffy: To be able to visualize it.

M: I'd also like to add that I think commerce on the Internet is much [inaudible], that product all over the world and they're less concerned about getting the information out to everyone.

Robert A. Duffy: Empowerment of the individual in a way. Sure.

Michael Palmer: Should we take one more question and then...

Robert A. Duffy: Yeah, take one more and then we'll break. Go ahead, sir.

M: I think people who work here are unwilling to put their money into on-line [inaudible] should turn to the left side and say "here's what you got, X number of pages." It's kind of penny-wise and pound foolish from my perspective, because I work for a company that does a lot of direct marketing, and if we could go on-line with all of our printing it would be unbelievable.

The problem is getting people who are used to doing mailing even though the [inaudible]. Let's put the whole catalog on-line; let's put the coats and the jackets so that you can see them at 360 degrees because you're paying money. Dealing with internal stockholders on that is really the key to reach the critical mass where you do have something on-line that really does represent your product, as opposed to saying, "Gee, we've got our catalog on-line," and you go there and there's maybe 5% of it there.

Robert A. Duffy: Institutions are amazing; some institutions are amazingly easy about spending six figures through a familiar channel even though the return on that investment is not clear to them or not consciously clear to them. But they fight like crazy and resist new modalities. That's really true, and I think that's part of institutional inertia. In another way your question almost sounds like a setup, because you're talking about tokenism. My personal opinion is that there's not just tokenism in catalog publication on the Web, but pretty much tokenism across the board.

The next site that we're going to visit, I think, is a case in point. Coca Cola, where they've given a certain amount of big bucks, I think in this case to their technology and Webmaster establishment to set up a site. It gives itself, at least on the surface, to a very specific audience and it's not about point-of-sale, but it is about selling in a way. Why don't we leave this up, as kind of the coda to this section.

Let's take about a five or ten minute break if you want to do so, and then we'll come back and look at the Coca Cola site and some of the communication modalities they use. Thanks.

[Tape change]

Michael Palmer: [In the first half of the session, we were] looking at the idea that identity, image building and communication were some of the more fundamental elements and value points to be exercised on the Internet. Now we're going to take a quick look at the Coca Cola site where, if we read some of this — I gotta be honest, I wasn't nuts about the idea of a Coca Cola trading post. It's like, "Welcome to our site. Buy stuff." This is clearly not a traditional corporate sales site, is it? What do we have here? "Welcome to our trading post." You see sports and entertainment. Look at that, every time you go you get something about the Coca Cola company. Let me go back and see what happened there.

The "World of Coca Cola Pavilion." Look at that. I always get this same tip here about the Coca Cola company. They obviously want me to learn more about the Coca Cola company. "Welcome to the business end of the site. This is the place to look for a message from our Chairman, or an update on your stock. Just click on any of the vending machine's hot spots."

That's interesting. Let's see here. We got stock and earning. Look at that. New York stock exchange information... This is clearly not a product solicitation. "Our Mission And Profile." My goodness. So there's a lot of information here I guess you wouldn't traditionally expect to find in a kind of way-cool Web surfer target site, although that front page sure looked like it. What do we have down here?

Robert A. Duffy: Did you note the lead-in to the mission and the way higher-ups?

Michael Palmer: Yeah, where was that? I didn't find that.

Robert A. Duffy: Near the business end of the site. Right here on this page.

Michael Palmer: I've lost it. I couldn't find it. Let's go back up here and go through the front door again. You know what? I think this page changes routinely. Anybody notice that?

Robert A. Duffy: As of yesterday they had a page there — I'm sure we could find it if we searched around — a page that said, in effect, "this is the page that the poo-bahs or the higher-ups insisted on our having here, so we're putting it here anyway."

This is the kind of disingenuous pose — a marketing pose — that we're talking about when we address the issue of communication and communities of interest, because they're going right for a 20-something Net surfer audience. You can bet that the Coca Cola management, when they approved the expenditure to put up this very expensive Web site, did in fact insist on putting elements like corporate mission there. You'll note that the tone of the corporate mission statement, by the way, is very pompous in the grand tradition of corporate mission statements. It's totally out of tone with the rest of the site, and that's because they insisted that it be there, I'm certain.

Michael Palmer: There's a little bit of opportunity for feedback. Several of you who we spoke with during the break pointed out that you could have taken advantage of this channel to obtain information about your customers. Look at that — two of the muckity-mucks of the Coca Cola company. Somebody suggested, "Tell us what you really think." You can help route your comments by using keywords like "Diet Coke," "women's sumo wrestling," etcetera. Well, who buys a lot of Coca Cola? There you go.

Robert A. Duffy: They're not dumb when they do it like this. They know that there's a significant market segment to be reached and probably this is the — they get the biggest payback from focusing on this market segment, because how many people in upper demographics regularly surf the Web and look at consumer companies like this? Not many. Did you mention this, Mike? The trading posts?

Michael Palmer: About the classified... I was just getting to that.

Robert A. Duffy: Well that's another community of interest, but it's kind of tucked into the nether reaches of this infrastructure here. There's a very great deal of activity among Coke memorabilia collectors, so they put up a section to appeal to them. In fact, trade the memorabilia on-line. This is a worthy attempt to reach that community of interest, but it simply strikes me that there's probably very little commonality between the way-cool Web surfers and the collectors. I may be wrong. And the collectors of Coke memorabilia — bottles from 1935, the classic year in Coke bottle, 1935 — I just can't imagine the typical Web surfer being interested in that kind of thing. That's a community of interest that's served out there.

M: [inaudible]

Robert A. Duffy: Oh no, no. I think it's very well done, but I was simply pointing out the logical disconnects in it. They all point to a consistent market focus, and it is very well done. I suspect — well, I'm almost certain — that you'll see a broadening of the communications base in sites like this and others. We'll see as time passes and there's more and more widespread communities.

Michael Palmer: As a rather large organization flying the Internet waters to communicate with their constituents, they're taking advantage of some of the techniques that are more

communication-related than commerce-related. So that's really our premise. They're building communities of interest. They're presenting image and identity. They're reaching an audience and they're tailoring information to their target audience — doing some things that are not purely commerce-related, although I guess it is somehow related. It certainly helps sell more Coke.

So with that, we're going to move into the communications section. Having exhausted commerce and perhaps spent a little bit more time on that than we might have otherwise wanted, let's talk a little bit about the audiences here to the Coke site. Who are they targeting? Well, people who are young and hip, the hip cybersurfers; people who perhaps are looking for a diversion as opposed to a hard sell. Anybody think you could find the Coca Cola formula there if you searched hard enough? That might be a little too confidential. Looking people who aren't wowed by the trappings of authority... Here's the place where we've got to send info to the mucky-mucks.

Robert A. Duffy: That's kind of a tactful way of putting the attitudinal sector there.

Michael Palmer: And then here are some of the special interest communities. As Bob was mentioning, perhaps there is a disconnect there, although you can consider that as an attempt to have tailored information spaces within that Web presence that were targeting two different audiences and segmenting it.

It might be better to build the interface in such a way that there's a clear path of entry into that segment, however. And this, of course, if I can sound like James Earl Jones, this is marcom, and that means marketing communications.

That brings us into a whole new realm. We started with point-of-sale, pre-sale and post-sale support. Now we're dealing in the realm of using information in a commercial sense to support the economic health of the enterprise — to sell. It's a pretty easy transition when we go there from getting lifestyle warm and fuzzies, which is really what the Coke site did to its segment of audience. It makes them feel like they belong in a community. They are providing useful information that's either geared to lifestyle like the L.L. Bean site, for instance, with its park search utility, or even more serious areas of interest.

There are people, organizations and professionals out there who want to use the Net and who want to use the Web to get information that's useful to them and valuable to them in doing their jobs. That's what we mean when we say that other segments are joining in. The different organizations and constituents that we're going to represent here are kind of a new audience. This is when you take it beyond the hip cybersurfer audience, take it beyond the rampant buying impulse people who want to buy that pair of sunglasses right away today and look at a very significant business application for this communication aspect of the external network.

For example, securities analysts. You know there are some sensitivities and that you have to be careful about the type of information that you might try to specifically target to this audience. But it is important to realize that this is a very influential and important group of people that you will reach, perhaps some opinion leaders, if you will, who in a very small group wield a great deal of influence in terms of positioning your organization and being leaders — I guess thought leaders — and describing your firm and its value in the marketplace.

Robert A. Duffy: Yeah, that's a key. That's a buzzword, but it's a key term, the notion of opinion leaders. And now we're moving beyond marcom even, into the realm of, for lack of a better term, public relations. But it's really about image building — transmitting your prestige as an enterprise to broader communities of interest. That's why these guys and women, media and

securities analysts, play such a big role in that. And they're coming on the Web; they're doing research on the Web.

Other sectors in there would be professionals. That's a catch-all, but what we mean by that is merger and acquisition scouts, analysts within corporations that are looking for alliances with other industry players. Those are just two examples, but I think if you thought about it, you could think of very many others in that same category. Institutional investors and investors in general — but institutional investors in particular because they carry more bang for the buck per transaction; researchers, either on campuses or people who are writing books, whatever. There's a great deal of value of expanding the information transaction in your Web space beyond marcom into the area of legitimately useful information.

Now, there may be a spin favoring your organization on that information, but it's still truth and it's still useful to the generally intellectually curious.

Michael Palmer: And again, some of the elements are features of new communication channels that make it so compelling for say, distributing catalogs, that make it even more compelling for distributing an organization's intellectual capital — information that backs up its identity and image, presents information about its vision mission and where it's going, and provides credentials perhaps by publishing research findings, etcetera in that sense.

How would you send ten thousand copies of your 50 page research White Paper out? Very expensively, of course. But why don't you make it available on your Web presence and maybe send out an e-mail to people who might have expressed an interest in learning more about your organization?

Robert A. Duffy: How do they do that today? If any of you read *Information Week* or *Computer World*, you'll see the ubiquitous full-page ads from computer vendors which say, "If you want our free White Paper on managing clients over on the enterprise or whatever, call this 800 number." And they're spending a lot of money on communicating ostensibly factual and useful information to traditional print channels. Mike is suggesting that the Net is a collateral channel for that.

Michael Palmer: Here we are back to our model of this communication process taking place. The principal changes from our last view in the communication model here, the point-of-sale, has diminished to almost a dot, really going way beyond that. We still have pre- and post-sale support operations taking place both through our network infrastructure and through the Internet channel, as well as through traditional channels.

But we've added some things on the bottom. We've added a new group of opinion leaders for the new audience members that we're trying to reach — industry allies, people that we want to collaborate with, perhaps, in our markets. And we've also added this thing called organizational knowledge, which perhaps Bob would like a stab at.

Robert A. Duffy: This is the simplest way we thought — or not the simplest, but perhaps the most useful way — we could express the concept of the intellectual capital of an organization. Think of it as the value of an organization's experience and operations over time. It becomes its knowledge base. There's a growing discipline in managing organizational knowledge. As you can see, it draws on — I hope you can see that we intend for it to draw on organizational information resources, on real-world operations, and to both draw on and be expressed through the network infrastructure. So when I refer to factual and useful information published by a commercial enterprise, I'm really talking about some of that institutional knowledge that we, as an enterprise, are trying to communicate to our diverse audiences — customers —

through opinion leaders.

Michael Palmer: This was helpful to me for comparison purposes, to think of organizational knowledge as the collective intelligence within our organization, made up of its people; the thoughts and the processes in our minds as members of that organization. The systems and processes we have in place are our manufacturing systems, perhaps our order fulfillment system, the way we handle incoming customer support inquiries or technical support operations, and distribution.

Organizational knowledge is all of the [company's] activities, both real-world and as embodied in our corporate management information systems. The organizational informational resources are really, to me, translations of organizational knowledge that take a form. They're a database. They're an application that helps our accountants keep track of our profit and loss. They're our print media, such as our annual reports. These are all elements that we've drawn out of the organizational knowledge.

Robert A. Duffy: And it evolves, and it changes, and it's very, very difficult. And perhaps more importantly, it's very, very expensive to capture in any comprehensive way. What we're talking about here is getting as much of it as possible and using the Web as a channel to get that organizational knowledge. Of course, it has to be kind of packaged. It has to be collated and packaged in effect. But putting it up on a Web server as a means of enriching the information channel — again, remember we started with pre-sales and post-sales and went to marketing communications. This is a much broader information channel now. And in effect, if you can get past the terminology that we use of organizational knowledge, it's already happening out there.

Michael Palmer: I think that another distinguishing feature that helped me understand the concept is that organizational information resource really, in a sense, withdraws from the bank account of organizational knowledge. The deposits that an organization makes in that knowledge are really the learning that takes place in the organization — learning about the marketplace; learning about the customers, the allies, the relationship building; personal learning and knowledge; recruiting, hiring and human resources. So that's the way that the organizational knowledge base is replenished, and there are some wonderful management texts on the whole subject. I believe discipline is one of the principal tombs in that arena related to the learning enterprise.

I think that the Internet channel, it's safe to say, is a way for organizations to accelerate and less expensively capture that organizational knowledge, and then leverage it by reusing it perhaps and making it available, both internally and externally, to the organization.

Robert A. Duffy: As we move into the collaboration segment, you'll see how that can, in fact, happen in organizations.

Michael Palmer: So the trend of all of these conjunctions of concepts and realizations, and understanding the value of this channel, is that the Web information available is becoming far more serious, and nowhere is that more obvious than the services sector.

Robert A. Duffy: What we should have said, before we show this slide, is “follow your impulse.” Groan or cheer based on the next screen that comes up, because I'd really like to know what your response to that is. Okay?

Michael Palmer: I heard one clap and one sigh.

Robert A. Duffy: They paid big money for that.

Michael Palmer: That was either because it's time for the session to be over, or...

Robert A. Duffy: We want to look at IBM very briefly because IBM does do a good job in this regard of broadening the information channel. So why don't we just jump in to their space? This is their welcome page. And what I want to draw your attention to first of all is the journalistic periodical model that they use.

You can read about their presence here at Internet World, if you choose, but they have a little bit more substantive stories there as well. These are not plain and simple news releases; they're massaged a little bit, and they're quite good. Now, there's a straight text story, but they use a far richer mode in other stories.

For instance, they're using hypertext, again reaching out with this notion of community service and communities of interest at the West Virginia public school system. We won't go there, but that's a leap out into cyberspace. And they use a fully illustrated — or somewhat illustrated — page in another, more marcom-oriented story. So if you wanted to find out about their activities, that's one good place to start in the IBM space.

Michael Palmer: It was interesting to me to see that the organization with the dateline banner for October really paralleled the kind of monthly newsletter, if you will. And like the Coca Cola site, things change very frequently.

Robert A. Duffy: Yeah, if the Web space is started with the concept of a billboard... Commercial Web spaces, I think, are rapidly moving to the periodical model where you'll have a dateline. Whether or not a lot of the material changes I think is less important than the perception that these sites give that the material is changing. You change a lot of the materials at the top levels, but keep the solid infrastructure elements there. IBM does a great job.

Michael Palmer: In a sense, that — the delta, or the change from one representation to another — is going to imply a change in organizational knowledge, that the organization has learned to stay in its leadership position, perhaps, in the marketplace. So this is a very good way of representing that the organization is continuing to learn and grow and hopefully entice outside entities who want to collaborate or place their trust in that organization.

Robert A. Duffy: More likely the latter, in IBM's case. Here's one interesting point; the stretch category that they have here. Organizations that have the means to do collateral marketing communications campaigns are beginning to use the mixed media resources that they developed there in their Web spaces. MCI is a case in point, with the Gramercy Press campaign. There's an actual Gramercy Press site on their Web space.

Here's IBM's version of their very clever campaign, in my opinion, "Solutions For a Small Planet." And you can get to storyboard versions of the individual commercials. It's interesting to me, as an Irish-American, that IBM is not very politically correct in portraying the only animal on this board. [What they have used] to portray these national identities is a sheep. That is, of course, the Irish commercial. The rest are all real human beings.

But you'll see this is storyboarded here. You can get the video; we're not going to. We don't have the help wrap-enabled here, so we can't go out and get that. But they have the script in the original version. The original version is very dialectical. It's not Gaelic, but you can even, if you choose — again, this reaching out to the outside world — you can go to other Irish

resources. You can go, if you're following the channel down to the Tibetan Buddhist portion of the campaign, to similar resources. You can learn Gaelic, visit parts of Ireland or whatever. Again, this is the company kind of reaching out to diverse communities of interest.

At the same time they are providing a putative service to Web surfers, but they're not fronting that as many of the early pioneers in Web space development did. They're tucking it back and attending to their corporate communications agenda up front, but doing it in an entertaining way.

Michael Palmer: So what we find in the Big Blue site is a return to the more core values of the Internet communication channel in presenting identity elements, image elements — things that are really informative communication. Naturally, we want to see more of the service elements available as well. They're a little short on the collaborative venture, but then not every organization has evolved into the full-scale, bi-directional communication that we believe is the kind of killer application here. But they certainly covered most of the other bases, and shied away from the pure kind of rush to commerce.

Robert A. Duffy: When you get a chance on your own, look into that IBM site and see how many of those elements are actually covered. We sort of rushed through it, but there's a good deal of serious material on their technology and on their community relationships as well, if you look for it.

Michael Palmer: So what are some of the reasons that IBM uses some of these techniques? Well again, to build an image, an identity, and to be a leader in providing this kind of information. The result is, overall, a very comprehensive look at the organization at a level that is representative of a very complex information universe.

I think we had a couple of comments earlier about interactivity being important. Nowhere is that more important than on the interactive services, because people expect to have at their disposal huge volumes of information, not just a couple of narrowly defined, pretty slick pieces. They want to have access to everything. They want to get right down into the heart of your organization. That's going to be a major challenge, managing the value of opening a broader, more open channel of communication with the external world through these mechanisms. How far do you go? How much do you open? Do you provide access to your internal on-line accounting systems? I don't think so. Do you provide access to your last 20 years of financial data and provide your quarterlies the day that they are submitted to the FCC? Absolutely.

In fact, it was kind of interesting to note that my firm actually was able to distribute the annual report for 1994 about three weeks early by distribution on the Web. We didn't have it back from the printers yet. That's very helpful to us. The information was ready to go, blessed, combed over, had gone through 17 different levels of approval and was wordsmithed by a host of thousands, and boom — it was finally out there on the Web a couple of weeks before it could even be sent out to our key constituents. So there were actually many institutional investors and other organizations and perhaps opinion leaders who were able to access that information through the Web.

So we're going really beyond purely marketing communications as we go on our communication chain to presenting real corporate know-how that is intellectual capital, which again, to refresh memories, capital is knowledge and experience embodied in the products and services offered in the marketplace; the systems that support those; the processes of — I mentioned a few of those before — customer service fulfillment, shipping, receiving, all these sorts of things; your research activities and your look to the future, what's your eye to the

future. And particularly in your human resources. We the people that make the organization are organic databases, I believe.

Let me interject something on human resources. The conventional wisdom or the old paradigm of Web spaces tends to dehumanize the space, and you see very few documentary photographs of people or information about people. But now corporations are beginning to do more and more of that. It's been a long time coming. It's a little surprising to me because in the other communication channels — in the print channels and in the television marketing communications channel — companies are very quick to promote their human resources and the notion of the people that work for them. IBM does this, and now a number of the other major companies that have fully elaborated Web spaces are beginning to bring in selected photographs of people and profiles of the people who work for them. To me, that's a very valuable human tool.

Where are the people on the Internet?

Robert A. Duffy: Look around. They're hard to find.

Michael Palmer: The list goes on and on. Everything that could be said to define an organization — but most importantly, that organization's relationships with the marketplace, with customers, stockholders, investors, capital markets — these are the areas that have been perhaps underutilized — real targets, I think, for tremendous return on investment on your external, perhaps Internet-facilitative communications strategy.

Robert A. Duffy: And there's a learning process in the interaction with these other entities that happens in the corporation and that becomes the fruits of that learning process, becomes part of the intellectual capital. It's tough to capture, admittedly, but it's out there, social entities being, say, art museums, public TV stations, charitable organizations, whatever. Although it's becoming a decreasing portion of their budgets, they do spend a significant amount of money in community outreach. And in fact, if you look at the Bank of America site, you'll see a number of profiled descriptions of what they're doing in the community. I think that L.L. Bean also has similar thing.

Michael Palmer: Yeah, principally focused on the environment and conservation.

Ah, relationships within the enterprise. As we move into our collaborative section, we'll talk a little bit about the Internet and those internal relationships and their importance at all levels to the healthy functioning of that learning process.

So this whole idea of an institutional knowledge, organizational knowledge and experience is one that has great value, but only if it's possible to capture it and disseminate it efficiently. It can be very expensive, and perhaps organizations have not leveraged the value of this repository of information in the past because of the barriers — cost, principally — to making that information available.

As we see the capabilities of the Web mechanisms improve, obviously there will be an explosion of new approaches to conveying, gathering, transmitting, sharing and collaborating on the basis of organizational knowledge. We have table here that kind of steps through time; if you look down the left-hand column you'll see a sort of a time-line approach to the variety of browsers and functional mechanisms available for retrieving information.

Robert A. Duffy: We just want to run through this quickly, but it gives you, I think, some sense of the evolution of publishing modes on the Web. Back in the old days it was just HTML, just raw text. And then in the early *Mosaic* stage, we could bring in JPEGs, and in-line — not JPEGs

in-line. But you could get JPEGs, audio — file-based audio, where you'd have to download it, the same way you would with video — and then it would play on a helper application, in effect. Page layout was pretty much dependent on how wide your window was and whatever in those days. Since then, there's an informed technology and related CGI approaches, image maps and most significantly, to me, the introduction of table capabilities.

If you're familiar at all with a widespread vision of the applications that are on the Web today, you'll see a remarkable use of tables to organize text on the page and to imitate, in effect, the printed page. We have one or two examples of that.

Michael Palmer: We're getting short on time, so I'm going to go ahead and summarize. The intent behind this is to convey the sense that the technology is certainly an underlying facilitator of the means of communication, and that as communication professionals there's a real challenge to employing and managing and taking advantage of these technologies. But it's really not the topic of discussion for us today.

We're really focused on the what and not so much the how, and there are other sessions in the conference that are very detailed and focused on these techniques and technologies, which are absolute incredible accomplishments. You see at the bottom here *HotJava*, kind of an enterprise-wide or worldwide global client server object intelligence mechanism, and virtual reality coming soon, here now in some form. This list will continue to grow and just run off the bottom of the screen, each time adding a new way of conveying those essential core competencies, giving a new way of conveying the intellectual capital, the organizational knowledge and sharing that, doing the organizational learning that we need to see happen to really continue growing in our markets.

Robert A. Duffy: But — have we made this point yet? I don't know.

Text. You can't communicate these things without text. Text is poised for a resurgence on the Web, and I think we want to give you an example, just a real quick one. *Morning Herald* publishes a Web edition. The article changes from day to day, obviously. It's often illustrated, but unfortunately today's isn't. But you can see this is a section — as they themselves admit — for readers, not browsers. You can get to this and read the story or use the table of contents in the right.

Again, this is empowered by the table technology that Netscape introduced. We kind of expected when we prepared this presentation that we would get a lot of resistance to the notion of text coming back on the Web. So to make our point that it's not just old fogies who read the text, we have another site here: "Bookmarks."

Michael Palmer: No, you grabbed "Go" instead of "Bookmarks."

Robert A. Duffy: Well, so much for drama. We're spinning. Should we reboot, or... You can't get to the options? Okay, well, the site that we had was The Spot. Do you know that site? It's kind of a Melrose Place on the Web, and there are about six 20-something residents who ostensibly live in this beach house in California. It's really all fictional, but complete with a selection of very attractive women and men — very vibrant, interesting 20-somethings. Each of them has a diary, and it appears not everyone writes every day, but every couple of days a given individual will write, so you get a progression in their lives. It's sumptuously illustrated, very beautifully laid out, but it's ultimately text-based. And it's clearly a very expensive proposition.

One question that we might suggest — it may have to be rhetorical because of time considerations — what's the commercial benefit of this? Does anyone know what these creative types are doing? How are they going to make money on it? Because they haven't tipped

their hand on it yet, and it's been going for about nine months. If you get a chance to go there, it's Web address is www.thespot.com. It's quite an interesting site, and I think it's been elected the cool site of the year — one or more of the ten thousand or so cool site of the year surveys that are out there.

Michael Palmer: Very briefly, I want to introduce you to the concept of the media architecture. This is something that my firm, American Management Systems, is forging ahead with as a both strategic and tactical means of capturing the intellectual capital and reusing that, repurposing it, transmitting it to cross-organization and to the outside world. The concept behind the media architecture is astonishingly simple. It's the idea that you can gather this information from a variety of sources that is representative of your organizational knowledge: multi-modal information, print media, audio, text, video, news clippings, what-have-you, press releases, etcetera.

Multi-channel is where it gets exciting. It's the idea that from a central repository, perhaps of this intellectual capital, you can instantly transmit, retrieve, sort, and otherwise process for public consumption, information in a variety of ways. As a concrete example, I may have my 1994 annual report, and I have a print version of it. I also have ways for people to not only get a printout and see that, but I have ways for people to get it through the Web. I have ways for people calling in on audio response to have a table of our financial results read to them. I have ways for people on an internal, perhaps touch-screen multimedia kiosk to access the various pages and information pieces or elements of that annual report.

But all of these channels are fed by the same piece of original data, so the idea is to really capture assets as they're created, to capture these media objects, if you will, and make them available through a variety of channels without having to painstakingly go back in and re-author, re-edit, tweak and primp and prepare for press whatever needs to be done.

The tactical vision is, of course, really to store this. It's probably going to be a type of object-oriented relational database, storing both media objects to the base level, as well as composite products — something like that 1994 annual report. I would be delighted to talk with you after the session in more detail about that. The real challenges again, are not the technology but the people, how you're going to get people to both look to these resources as a source of learning and information readily packaged and available, how are you going to get people to collect this and transpose it into reusable formats.

Robert A. Duffy: How you're going to organize and pay for that, really.

Michael Palmer: Exactly. So again, technology, like the Web, Internet and media architecture is rarely the deciding factor in whether a new way of accomplishing something is processed as business, etcetera. It's really going to be valuable. It's really the people that need to adopt it. So a change of management is an incredibly important arena.

And that brings us to the final section of our presentation: collaboration. We've hinted in a great deal of detail the value of communicating by directional communication. We're just going to step up the ladder one more time to say lots of bi-directional communication can be used for lots of tasks and processes in a way that brings people and products and services and organizations together.

Getting back to our model, you can see that we have some clouds here. Up top, within the organization, we have the Internet and the idea of internal webs providing information. Sun Microsystems is already forging ahead, providing most of their internal accounting information to departmental managers through an internal web kind of hiding behind the firewall. It's a very exciting concept because for the first time we may have a real network standard TCP/IP to use

in a real kind of interface standard that's multi-platform.

We don't have issues like, "Are you on a Mac or a PC," or a Sun Box, HP Box, whatever you might have up your sleeve. At first I think it's going to be supplanting existing corporate information systems. But the real value, the real revolutionary value to be had, is in facilitating organizational learning so that the capture of intellectual capital — the capture of intellectual organizational knowledge — can take place efficiently, inexpensively and rapidly so that information is disseminated and put to good use as quickly as possible.

Bob, perhaps you'd like to comment on the Virtual Collaborative Net.

Robert A. Duffy: The Virtual Collaborative Net is simply a virtual segment of the grand Internet. It includes what we have up there — industry allies, partners in joint initiative or multiple party initiatives, partners, suppliers, market outlets; if you're a manufacturer your wholesalers, your retailers, your sales agents, whatever. The Internet provides a marvelous tool to bring everyone together in a collaborative effort. Not only does it open all kinds of opportunities for virtual corporations, but for virtual initiatives in which the parties come and go and change as the initiative matures and succeeds.

Michael Palmer: So with these "intra-nets," we will look to create an environment for broad-based participation in the life of the enterprise through discussion groups, organic databases.

Robert A. Duffy: Organic databases being something like the Lotus Notes or the IBM Notes model. There's a great deal of activity going on now to kind of supplant that mode with intra-net or intra-web oriented collaborative databases that grow from the experience of the people that participate. Discussion groups are a parallel.

Michael Palmer: Of course, departmental Web space is sharing perhaps financial and production information which leads you to the rapid collection and collation of intellectual capital, and then being able to reuse that, repackage that, into your work product.

Robert A. Duffy: Think about the notion in a large organization of letting the departments do their own Web spaces, where they can't do much damage in terms of outside audiences, where you can kind of get those spaces, compare them, fix them and bring them up to speed before you make them available to the general public. Think about the kind of rampant — this may be too harsh a characterization — amateurism that characterized a lot of corporate Web spaces in the early days. This is one way to prevent that from happening, to allow the collaborative energies of the enterprise to come to common cause and to come to agreement on how the Web spaces should look, and work them into the public Web spaces.

Michael Palmer: Of course, being able to do these things really means that that intra-net becomes the lifeblood of the company — managing human resources, managing your projects initiatives and allocating resources. I mean, think about the opportunity to build virtual work force capabilities. Why relocate staff when staff can relocate virtually through collaborative techniques on the internal networks?

Robert A. Duffy: Everyone doesn't have to be in the same place to participate in the same initiative. How many people are currently using audio conferencing on a routine basis? Video conferencing? Not as many. How about screen sharing? Application sharing? A few. That becomes more industry specific, although it can be said that even for design firms' product management, many of these techniques are available today that are facilitated by the internal

and external networks, and a considerable value to be had by building these virtual work force capabilities. The external networks, of course, are the embodiment of an organization's relationships with the outside world. You do the same things with those that you do internally, but with a different group of allies and partners.

And to borrow a term from the Japanese: koretsu. This is kind of koretsu at large, koretsu squared, where you can collaborate with other organizations but you don't have to be wedded to them for half a century. Virtual collaboration.

Michael Palmer: So to conclude, we started with a view of the world that was commerce-oriented — purely mercenary transactional buying and selling of products and services.

We added to that to include more of the communication aspect, perhaps supporting some of the more traditional functions of customer service and support sales and marketing fulfillment — information about an organization's image, identity, communication aspects, reaching opinion leader audiences.

And we wrapped up with the collaborative model, where all of these things take place and the organizations that are looking forward and are smart about this will be capturing the results of these processes and activities in their organizational knowledge banks to continue learning and growing well into the next century. Thank you all for coming today.

PUBLISHING ON THE INTERNET COPYRIGHT — LAUNCHING CONTENT ON THE INTERNET

SPEAKERS

David Bernstein

Vice President, Marketing, Electronic Publishing Resources

David Van Wie

Chief Technical Officer, Electronic Publishing Resources

David Bernstein: Thanks for coming to Session: “Launching Content into Cyberspace.” My name is Dave Bernstein from Electronic Publishing Resources. We’re going to talk today about putting content on the Net, and the interesting copyright challenges that poses and some innovative ways people have set out to solve them.

I am with a company called Electronic Publishing Resources from California, where it is slightly warmer than it is here. But nonetheless, we are a company dedicated to the development of technologies that solve exactly this type of problem. So I’m pleased to come speak to you today on the next frontier of the Web, which is actually getting good stuff out there that rights holders feel okay about.

The issue we’re talking about here is digital content. This is where digital information is the product. Now, obviously there’s quite a bit of commerce on the Web happening today, where you go ahead and purchase an audio CD or a video tape, and once you get your credit card number across and so on, then FedEx arrives tomorrow with the product.

But it’s a whole different game if the product is delivered digitally, isn’t it? Because it comes over the wire and then you have it — or at least that’s the current school of thought in most people’s experience. But when digital information is the product, we really see a whole other interesting set of issues, problems and challenges, and a whole new world emerging that really enriches our use of the Web and makes this whole electronic commerce information commerce, which is an important new kind of approach to this.

Where digital information is the product, we obviously have some key applications: electronic publishing in the normal sense of newspapers, news, books. Publishing, of course, is not restricted to simply text; [there’s] publishing of audio, publishing of video, multimedia, publishing of interactive works, business information.

Obviously the electronic media, the Web in particular, is a very appropriate media for delivering highly timely and very important news items. In terms of business information, it is often very, very valuable. Market studies, stock quotes, competitive information, product reviews — these are things which the information-providing companies spend a lot of money putting together that you count on for your business, and you want to be assured that digital product is delivered to you not only completely but also with integrity, so you can trust it.

Clearly, interactive multimedia is something that is mostly digital, with CD-ROMs and so on. And we’re going to see this delivered over the Web and the Net more and more as bandwidth increases. Computer software [will be delivered] in a way beyond the shareware model, where software is delivered directly, and [you’ll have] entertainment products, typical movies, and audio, as I mentioned, from the whole recording industry. And all of these things really are in digital form.

Now let’s figure out how to actually get them in electronic media as opposed to waiting for FedEx to deliver the physical version of this product. It’s worth thinking about how these things have multiple delivery vehicles. You can obviously expect to get these digital products over the Internet, which is great.

CD-ROM is something we’re all familiar with, in terms of interactive media, multimedia products, in terms of software, in terms of reference materials. Clearly cable, broadcast and

satellite TV are other mechanisms whereby we receive digital information. The DSS Satellite System is one example of a direct-to-home digital information delivery mechanism. Private networks and dial-ups, such as the major on-line consumer services, are an example of this.

And combinations. Now, this is quite important when we start considering the richness of digital information. When you start looking at products, for example Microsoft's *Baseball* that comes on a CD-ROM, for which you get updates on-line, or other combinations thereof where you get software on a CD but updates on-line, or products that come on CD and then additional information comes through the Internet. So combinations of media as a delivery mechanism for digital products is something that's very important and will emerge as very important. Things like entertainment products on these high-density CDs will come out, but you'll want to pay for them over the Internet. So this is the world of digital content.

Information commerce is digital content that's delivered in some kind of a secure way so that you can treat it as a product. Now, what this means is [you get] the digital content plus some way to pay for it in a secure fashion. Clearly that's the commerce angle of information commerce.

When you really start considering, how do I get digital information now? How do I get information now when I get an audio CD or a publication, a multimedia product or a videotape? That sure has had a large value chain behind it. This is important, because I don't actually buy the book today — a book, a physical book from the author. I buy the book through a rich value chain, from author to publisher to distributors of the book to retailers and so on. There's a whole value chain that happens in commerce. And obviously, the same thing happens with software. The same thing happens with entertainment products. The same thing happens with most products, and information products are, of course, no exception.

There really is a value chain, and that really requires some way to enable multi-party transactions. So one of the interesting aspects of information commerce is not only digital content and a way to pay for it, but a way to enable a value chain, mirroring the way we do business today.

Clearly, something very important in the whole world of commerce is information about how the value chain is running, and this is the sort of back-channel, or exhaust, of marketing and usage information that's so important to making the whole value proposition work. If there's an advertising model along with the product, or some kind of a coupon, that all relates to the value in what you receive.

The demographics that a subscriber list yields is a very valuable piece of information, and this is quite simple if the newspaper is thrown on your driveway each morning. But of course, it is much more complicated if you're going ahead and surfing the Web and buying your digital content that way.

So all of these elements add up to information commerce.

What we're going to look at is how we can enable information commerce in this context. Well, we need some new pieces to the equation — new pieces above what we have in the Internet world today — and that is protection of copyrights and this notion of licensed uses for the properties that are launched.

In other words, when somebody spends time and creates value and puts it into a digital form, then they have some rights in that product. Well, it sure would be great if their copyrights were respected, if they got paid or whatever, or other requirements. That way they could go ahead and launch their content into these digital domains and it will meet the criteria that they've established, since they own the content.

There's got to be some way to get paid efficiently. Now, we say "efficiently," and we use this word "micro-transactions," because if you think about it, some digital content, like an entertainment product like a movie, or a large whole body of research work, is probably pretty

valuable and worth several dollars or more. And that has enough value to it to sustain an entire transaction, which may have an overhead of a dollar or thirty cents or twenty cents associated with it. In fact, most credit card transactions or on-line systems today do have some overhead amounting to north of twenty-five cents.

A newspaper article or some other small piece of digital information, or maybe just listening to an audio product once, may be less than a few dollars worth of value. And so therefore we have to figure out some way that we can market digital content over the Net, understanding that we have an overhead in terms of a transaction and allowing people to buy products for one cent, a tenth of a cent, a hundredth of a cent, whatever economic models work. We need some way to get paid for these teeny micro-transactions that add up. Millions of people seeing one article in one newspaper adds up to a reasonable amount for the author to get paid for writing it.

Clearly, collecting usage information is something where we've really only hit the tip of the iceberg with the notions of the different hits on Web pages. Now we're talking about actual, real usage information of the digital content, and this is something that's extremely important so that creators and distributors of products can understand how people are interacting with their content.

If it's a magazine with some advertising in it, are ads being viewed by readers? This is an important component in the whole model of advertiser-supported publication. If it's an on-line catalog, what areas of the catalog are people shopping in? What areas are they ignoring? And clearly that is very valuable. If somebody spends time on a particular ad, then that advertiser would pay for that data so that they could send them follow-up information. It's lead-generation; it's this backstream marketing usage information that's very valuable in the whole world of making information commerce work.

Clearly, ensuring advertising [is important]. If somebody opens a newspaper, there are the ads and they see them. But how do you do this on the Web? How do you make sure somebody actually reads the ad before they view the content? Maybe that's the business model that the creator has put as a requirement for launching their content: check out this ad and you can watch this movie for free. Likewise, [there is] support for both traditional publishing models and new publishing models. If we can enable all these kinds of requirements and add them to the notion of digital content, now we're really starting to talk about information commerce, bringing the notion of buying, selling and processing information on-line.

Let's just take a look at how different this new world really is by first looking at the way it is today. This is the classic publishing model where transactions and control go through a central publisher; and when I say publisher, this can really apply to traditional print publishing as well as publishing of different types of multimedia, software or what have you. But certainly central publishers' clearing houses and financial institutions really are at the center of the way information is distributed today.

There's the publisher, and the customer will go ahead and get the product from them, and there will be usage information and billing and the financial institution will deal directly with the publisher to get some remuneration there.

Here, by way of example — and I'll use a newspaper subscription as an example — you pretty much get bulk distribution. This means that you get the whole newspaper thrown onto your driveway, or the whole magazine, regardless if you really want to read all the articles there or not. You go ahead and you pay for a whole month's worth or a whole year's worth of newspapers, and that's pretty much how we do publishing today.

The rights are enforced by contractual and legal agreements, which means that it's pretty much expected that you won't go ahead and copy the newspaper and hand out physical, xerographic copies of the newspaper to all your friends in the neighborhood. It's protected by

copyright law — and by legal agreements, if it's a more exotic product. If it's a research report that you've ordered or you subscribe to, then of course when you buy that research report you pretty much say, "I won't copy this and distribute it. It's for my company or my personal use only." Business newsletters are also an example.

So really there's a complex set of legal agreements behind all of this. Of course, the writers who contribute articles to the newspapers are also bound by legal agreements between them and the publisher; and so we've created a whole series of legal agreements which govern how all the rights of the various parties in the value chain are put together.

So really, there's only physical disincentives. In other words, it's a hassle to copy a newspaper, and so you probably won't do it. Likewise, a videotape copy is a hassle and it doesn't turn out to be really a great copy anyway. So you know, you really could go ahead and violate these rules, but it's mostly a physical disincentive.

And then, of course, after-the-fact compensation and reporting to the value chain means that after you've gone ahead and paid for your newspaper subscription then eventually everybody back upstream gets paid and they can some day, months later, get the demographics and the subscription information.

This is today's world of information commerce and by and large, across industries, print publishing or entertainment products, this is how it works.

Some people have taken additional steps in terms of trying to move this a bit into the digital domain, and let's reflect on some of the current state-of-the-art technology and see how well this answers some of the problems on the digital information commerce requirements we set out earlier.

We can go ahead and lock or unlock the content. I can deliver this encyclopedia or this demographics or this digital product on a CD, all encrypted for example, and then when the user pays me I can unlock it and then they have access to this. Of course, now they have access to this completely, so once it's unlocked they have the content.

Likewise, if I license-manage the content — in other words, I'm allowed to access it for a period of time or a number of usages through a license manager, a network license management sort of scheme, likewise the content is unprotected. So now I have it; I have it on my machine and I can do what I want with it. I can save it, I can post it, I can put it on my own Web page — and we all know what happens to it then.

There really isn't a pay-by-use model or any kind of usage or data collection in these schemes. I might have a large body of digital work, and I've unlocked it, but I really don't know what parts people are using. I really don't know how many people are using it or how much they're using it. And these schemes are usually pretty strange business models. Like you can use my information-packed CD for a year for \$5,000, and I don't really know if a single user is using it or if he's put that CD on his corporate LAN and ten thousand people are using it.

So this is not really great. And besides that, license management schemes usually require some kind of LAN. They have quite a bit of overhead associated with them in terms of administrative issues, and those of us in the business know that that's really not a very sophisticated security mechanism. It's very easy to spoof a license manager.

So let's look at some more recent things that have emerged. They protect the "wire schemes," as we call them, and this is a way to ensure that when information goes from point A to point B it can't be taken while it's in transit. And I think we've all heard of various schemes, SHTTP, SSL, from folks like Terisa and Netscape, and there are some others. These are more or less software renditions of the hardware crypto-routers that have been around for some time, and they are basically a great application of cryptography. [There are] two problems, such as Sockets-based TCP/IP communication or Web-based communication, but they are usually specific to a particular type of transport; it's pretty hard to use SHTTP on a CD-ROM-based

product, for example. And what it really does is it secures the transmission of content from one place to another.

So it really doesn't end up protecting the content. The content and the information are released in the clear at both ends. In other words, they're in the clear somewhere when they leave the author's desk, and it goes ahead and becomes encrypted and protected. Maybe payment is assured, and it is probably. It's actually a great way to make sure a credit card number gets from point A to point B, but as we've seen, rights holders and users are left unprotected. In other words, the content is released in the clear on the user's workstation, and if I use these same schemes to encrypt the user's usage information my private usage information is now left in the clear in some clearinghouse server. So although I've ensured that it hasn't been intercepted, if these are implemented properly I still really haven't solved the problem of whether the content is being used in the way that the rights holders want, and whether my usage information is being used in the ways I want. So [those are] good approaches, but strictly first generation.

There have been some initial technology approaches doing what we call "information metering." A few different vendors are mentioned on the slide here who have implemented some kind of a pay-by-use with usage data kind of technology, usually associated with some particular type of information delivery: for example, a CD-based information metering. So I can now supply the CD with a bit of hardware that will meter the amount of information I use off of the hardware, and likewise some other kind of scheme.

These usually require some hardware token, like a smart card or a black box that stores this information, and that's a bit bulky. They usually include a specific clearinghouse or business model baked into the system, which limits the way people can cast a business model. It really doesn't implement the value chain, and that's really still what we're searching for, this general-purpose, multi-party, value-chained way to launch information out there into cyberspace.

So here's what we need. We need some kind of enablement for these traditional commerce practices in the electronic space, a chain of handling and control and some way to enable ad hoc agreements. In other words, I like something that I've gotten and I want to pass it on to somebody else, and I just want to make sure I'm not disrespecting any of the rights of the value chain as to how the information got to me.

I want to go ahead and allow independent roles in the — rules in the value chain so that I can go ahead and say, "Well, I found this information. I'd like you to let me know if you're using it or not, or put an additional price on it."

The way to do this is to encapsulate the content in a container of some kind; in other words, protect the content, not the wire. This is an important revelation that we've had, and now a few other people have caught onto it in this world: that you really need to take the content, the business rules and the usage information — the "exhaust," we call it — and package these things in some common, protected form of transport that can sit on top of whatever media or wire it moves around in, some kind of container technology that protects the content in a persistent way. Of course, what this will allow us to do is integrate this notion of this protected content and protected information container into a whole end-to-end integrated fashion. It will give us some efficiency and some automation, but most of all we'll get some good stuff on the Web, because people's rights will be protected.

We can enable this kind of new electronic publishing model where we have direct value chains for delivery of products so we can get new models like customer-to-customer delivery of content, which in the traditional publishing model is basically illegal. But we would like to enable that in the Internet world — the passing on of information — while whatever rights and billing and so on that the original creators have put on it is respected.

And so you see this model where authors go to a publisher and then we can get all kinds of different value chains involved here: customer- based distribution or “super-distribution,” as this is known, multiple relationships with clearinghouses, value chains here, and also the ability to cut and paste so I can take information I like, take a part out of it, put it into my own document, redistribute it and the original author of that piece I took will still be compensated or his rights will be respected, whatever the case may be. This is the new electronic publishing model, and this is the way the Internet works.

And so we’ll go ahead and take a look at what this container technology looks like to enable this. What we’ll get in this is this notion of targeted distribution and micro-payments. Remember when we talked about the newspaper subscription, and I got the whole newspaper plopped on my desk, or rather on my driveway? Here I can just take an article and pay for it. That seems pretty obvious. But I’ll get rights enforced by the computer system; in other words, I can’t just pass this on to anybody because it’s owned by Associated Press or Reuters or somebody else, so I can go ahead and have some kind of cryptography or security mechanism included in this scheme that allows rights to be protected.

Compensation and reporting needs to be built in into the system. So when I go ahead and view this article, whoever needs to get paid or reported to gets paid or reported to, and it’s not a big deal for me as the user.

The interesting thing is that this goes ahead and enables new business models. It now allows anybody to package information in containers, to move it around and to use a variety of paths that don’t restrict a particular business topology because all I have is A-to-B security.

Now my company, of course, has this technology called *InterTrust*, which is a virtual distribution architecture enabling this type of container technology. We call this container the “Digibox,” which is something which can hold content, control information, financial information, backstream marketing information, all the information and the rules and controls necessary to implement this type of system.

What we have announced here at the show today is something called *NetTrust*, which is a product based on this technology for the Internet and on-line services, allowing people to launch their content into cyberspace in these Digibox containers, and have them have persistent business rules and controls associated with them.

This really provides for the first time a multi-party way to get content out there on the Internet and other networks. And as you can see here, it is 100% buzzword-compliant in terms of what we’ve put together.

A diagram of how this might work is [one where] I’ve placed content into a container; I’ve placed control information into the same or a different container and I want to move these things around amongst the different information appliances involved in the system. This might be a Web server, this might be a *Mosaic* or a *Netscape* client; in the future this of course could encompass other Internet access devices such as set-tops or PDAs, and there’s a bit of software that runs on each machine, participating in this system which understands how to deal with these containers. And these containers can move around in whatever topology is necessary and make sure that all the information goes to the right people in the value chain, and that people get compensated if that was the rule and that the rights are upheld, because the information never leaves the container and is never out in the clear and so therefore content holders, people who we want to put their stuff on the Web, can now do so with this technology.

Just to give an example of how this might work, here you can see some rules and controls in one container, some content in another container, indicated by this camera and this little audio wave and some books. These things can meet up out there in cyberspace. For example, maybe I get these rules and controls from one place in the form of my pre-authorized

credit card, or maybe I get the content from a Web site. I could process it, I could use it, I can pass it on to my friend. They can process it and use it; maybe they pay with a different payment method. If they like part of this they can extract part of this, and it's still protected. They can pass that on to someone else. And voilà — we now have a bunch of great content on the Net because it's protected in a persistent and permanent way.

The way this container looks, just sort of a brief overview, there's quite a bit more to this type of technology than simple, point A-to-point B encryption. You can see here that the content container holds information, it holds permissions, it holds things like budgets and methods, to allow for virtually any type of business model.

This whole notion of these rules and controls in this part in the middle here is very much a completely programmable system. I think we've all watched how fast the Net and the Web have evolved over time. It's very important to separate the business rules and the way people will do business from the actual content itself, because I'll tell you, we'll be here at this show next year and there will be a lot of different business models not even contemplated this year, and that will happen again and again. So we really want to get content into a container and express business rules in such a way that it's independent, so it's not baked into the system in an unchangeable way. And so you need to do this in an object-oriented system diagrammed here.

For example, I might have a property here which might be a encyclopedia — let's say a 1995 encyclopedia with a control set, and which has some kind of pricing. And [there's] another property which doesn't have a control set associated with it, maybe it's a World Book Almanac. I can launch a second container later on which goes after I buy the World Book, and I enable this with an additional control set, and by buying this World Book I've now gotten a discount on the initial encyclopedia.

So these are some interesting things you get when you have a container technology and you have independently deliverable rules and controls. I could send out in another — when it's 1997 and the World Book and the encyclopedia are still useful to some, but maybe can't command the same price that they did when they were leased in 1995 — I can send an amending container out and lower the price once those [with] the content is launched. Because once it's launched, I don't have it anymore. It's out there on the Net. So this is a very flexible and robust system.

What we've announced at the show today is something called *NetTrust* for Internet-based publishing. What content creators do is take a packaging application, dump their content into it in whatever form it is — HTML, Acrobat, MPEG, whatever — put it into a Digibox and then go ahead and use a rights editor. Creators can go ahead and say, "Well, here's how I want my content used, and here's how I want to get paid for it," or "Here's the usage information I want." They can then go ahead and put that directly on the Web or enable a value chain. In other words, the independent author may say, "Gee, who's going to visit my Web site? I'll make a deal with some large Web site to go ahead and market my content." And of course, that Web site can go ahead and further use the rights editor, uplift the price, add different payment methods and so on and so forth, enabling a whole value chain.

We have a tool which then slams this right into a Web page so that people can access it easily. Then users can go ahead and access this stuff by downloading some client software, which integrates in a number of different ways, although you can envision it as a helper application to a *Netscape* or a *Mosaic*. So it's very transparent. You can either link to it directly or use *OLE* to access the interfaces to existing browsers, and we'll show this with *Netscape* today. What you get is a whole secure transaction processing environment downloaded onto your desktop, and this enables the micro-transactions to occur. It enables the business rules to be respected and so on, and of course a clearinghouse application based on some leading

relational database systems which allows clearinghouses then to process the usage or financial information. So that's what *NetTrust* is.

How this works on the Internet I think is pretty obvious. The authors go ahead and place their content, using business rule templates, into a container using, for example, a Windows application. They might give this to a distributor or aggregator who is a large Web site, who may uplift the price or what have you. Now, note that when the container left the author's desk it's protected, because I as an author probably feel a little squeamish about giving my content to some major Web site. Is it really going to be protected?

This allows me to have control over my content; and then people can access this through standard Web sites, downloading some software if they need the helper application the first time. It's really quite more extensive than a helper application, but that's what it looks like. And then they go ahead and access content. It's really quite transparent to them, but they are respecting the rights holder's rights there. Then, in whatever business model the repository has set up, they go ahead and pay for this report usage and so on and this finds its way to the authors if necessary, to find the usage information they have specified.

So what you really now see is a value chain, which is very different than simply client and server kind of information vending. It's a much richer system that we really think will help enable content on the Web.

This is not something that is competitive or overlapping with some other technologies; this is something that's complementary with some of the payment systems you've heard a lot about that are out there. This is complementary to the electronic funds transfer type of technologies. This enables this super-distribution or launching of content onto the Internet, so this is complementary technology. We think it's a really important missing component to the whole way we want to buy and sell and use information in digital forms.

There is obvious huge list of millions of ways that protected content can be used. Today we're focusing on our *NetTrust* Internet product. Here, we're at an Internet show. I should let everyone know this is exactly the same problem that people face in the broadcast and cable TV industry, where these high, high capacity CDs are starting to hold digital forms of entire movies. Content creators are very nervous about this. Clearly, this is the whole notion of information databases and so on being provided in digital form, and this is exactly the same problem. So it's nice to have a standard container that can hold content on any medium.

By way of conclusion on this section, you have to protect all the information and all the transactions. We think that not only does the content have to be protected, but the rules and controls and the integrity of the content must be protected, the usage information must be protected. There's a lot more to it than protecting the wire. We have to support lots of different evolving business models and real value chains that we can't even anticipate today. Anybody who tells you they know how business on the Web will be done even two years from now, you should raise an eyebrow about. And clearly, the way the Net works, [there is a lot of] passing on of information from one individual to another. You'll hear a lot throughout this conference and coming up about some standardization efforts on these content containers; we really need to get an environment on everyone's desk so that people can go ahead and have a secure environment on the Net, and also create an infrastructure that allows for this to happen.

So next we'll show you a couple of screens of what this really looks like.

I'm going to introduce my colleague, Dave Van Wie, our Chief Technical Officer, to go ahead and do this.

And I apologize — the on-screen versions are quite hard to see here. Unfortunately, it's kind of a low screen, so I'm going to switch one of these to an overhead on my right here, which is somewhat easier to see. So bear with us.

David Van Wie: While Dave gets this set up, why don't I introduce the segment we're about to move into here? As Dave indicated a moment ago, we're showing you some shots from the user interface that goes with the *NetTrust* application suites that we've announced at the show today.

This first slide that he's put up there shows a portion of the user interface manipulated by the creator. And in our models we've really worked quite hard to make this process as straightforward and as automated as we could. In this example here he's showing you the portion of the interface where the user would go ahead and identify the content that they wished to put into the Digibox, as well as attach some descriptive information that would follow that content around.

Now, since the heart of the value that you're delivering is encrypted, it's important to be able to attach marketing information to that as well as simple abstract information, so that people are able to make a buying determination without actually digging into the valuable part, the "for sale" part of the content. And he'll also identify a template that describes the business rules that go with that particular category of content. This allows you to radically simplify all of these mechanisms that Dave was speaking to earlier, which actually — and when you really think about how your businesses operate, there's quite a few nuances and quite a few details, but normally you can apply those nuances and details again and again to different pieces of information.

Why don't we move on?

In this slide here, we're looking at the distribution rights, because it's critical in order to enable these kinds of value chains that Dave was speaking to earlier that you be able to describe how it is that value chain participants can manipulate the business rules that you've set out for protecting various usage activities with respect to your content.

And so here we've gone ahead and identified — we've got one of the screens up here that shows a few of the business rules that you're able to establish over that value chain, including the ability to identify new events that you may very well want to charge for.

Let me give you an example of that. An aggregator may make a determination that they're willing to go ahead and foot the bill in accordance with the publisher's business model, because they may have an aggregated value. For instance, if some content provider wished to charge, for example, a dollar to access a piece of content, an aggregator may go ahead and subsume that into a different model. Maybe they pulled together fifteen or twenty different pieces of content and they want to rent that to people for \$2.50 a month. This describes whether or not you as a provider are willing to participate in that type of a value proposition.

Let's move on.

As I indicated earlier, some of the business rules that are involved here can initially appear to be quite complex; so what we've done is we've used the power of graphical user interfaces to go ahead and present this to people in a comprehensible way. Here you're looking at a screen from our rights editor, which permits a user to go ahead and identify all the categories of user activities that they're interested in, either for collecting usage information, enabling or disabling, as well as attaching pricing models.

So in this case here you start off on far left, identifying a usage activity. In this case I believe it's an "open," but it's hard to read from this angle. So when somebody opens up a package we're going to go ahead and follow through the rest of a transaction.

Now we're going to step into a metering phase of a transaction, where we're going to record some of the usage information. Now in this model I believe we've gone ahead and said that we're going to record a transaction each time the thing is opened. Other models would include just keeping a record the very first time something was opened, or every tenth time something was opened.

[Tape change]

David Van Wie: The second stage or the third stage is that of the actual billing activity. Here we've identified something quite straightforward, where we're going to associate a simple price with this particular transaction. Now we can do things that are significantly more sophisticated at this step if our business model calls for it.

For example, in the software industry people engage in suite purchases all the time. So at this stage, you could base your pricing decision on information that's elsewhere in the user system. For example, that they already own rights to use other software packages.

Another model might be that you want to have a competitive price. Certainly, a more practical model in the global environment of the Internet is to allow people to pay you in different currencies, so you can establish different rates or conversion rates for different currencies at that step.

So as you can see you can start off with something really quite simple, but as you explore the subtleties of real-world business models different factors can come into play. That's why we felt it was necessary to produce a generalized programmable system that lets you actually describe your real business.

It's also important to allow you to capture all of this into a template, as I indicated earlier. You certainly don't have to do this every time. Once you figure out the model that's appropriate for categories of content, you can reuse these business rules over and over in container after container.

Let's skip this one, Dave.

Okay. Now here I'm indicating a modification that might occur in the value chain. As I described earlier, we had a transaction starting off with a particular type of usage activity — in this case, opening a container. And then we're going to keep some records about that, and then we were going to associate a pricing structure. Now, in this model here a value chain participant, an authorized distributor, has added their own rule. In this case here they've split out of the metering activity and are establishing their own price for that particular action.

There's some important concepts here to include in any system like this. It's very important that the user's experience be that of the final value chain participants, so that the model that the user experiences is the one that the person who's directly interacting with them has defined. So in this case, the user will transparently see the aggregate of both of these different billing activities. However, there is adequate information collected such that this can be sorted out, either by that last value chain participant or by some third party, some clearinghouse somewhere, that sorts out all of the various payments that go to each of the parties.

We've described to you a little bit about how we would prepare this content, and we talked a little bit about how we would identify content to put into a Digibox, the categories of content that were out there. Dave spent quite a bit of time discussing that. I've been showing you some of the application software that you would use to package a Digibox and some of the graphical tools that we would use to describe the business rules that go with that.

In this screen here we've gone ahead and taken a simple example of how this might appear to a user — what the user's experience would be of this type of an environment. So we've established a WorldWide Web page here and you'll see that there is a piece of content indicated as an icon on that screen. You also see across the bottom there a collection of our system software churning away in the background.

As Dave indicated, from the user's point of view, our system in that landscape appears as simply a helper application. But these generalized tools lie in the background.

Go ahead and move on here.

I suppose an important point with respect to that is if you wish to add a CD-ROM integration later on, the user doesn't have to change the basic tools that they've been manipulating all along.

So once a user's clicked on that content — here, I'm going to bring you through a couple of user interface screens. These are all configurable so the user doesn't have to see them every time; but since this is your first time we've gone ahead and turned them all on. The first thing that the user is asked to do is to make a decision about how they want to register this content, which parties they want to interact with to perform payments as well as which collection of business rules they want to apply.

An important capability here is that this model allows you to define different categories of usage activities — different classes, if you will — such that a user who wants to take a trial run through your properties can go ahead and use one set of models. For example, they may pay a single, low rate to use a property once, and then you can also package in there a set of business rules that would describe purchasing broader rights to the property, for example, so that they could use it an unlimited number of times as long as they did so in authorized ways. So that's the first interface that's presented to them after they've clicked on "consist-sub" in this particular integration.

After they've successfully made use of the content they have other tools that they can use to look into their system to see which Digiboxes have arrived there and what their rights are in those particular Digiboxes. And then it's almost accumulating usage information, which is seen down in the lower right.

It is very important that these things be done in transparent ways, such that you don't interfere with the user's experience of your content.

Once they've gone ahead and registered the content, or if they've made a set of generalized decisions about how they register content — for example if they always want to pay with their VISA card and they always want to work on a pay-per-use model, they wouldn't have to experience any user interface interaction at all throughout their Web surfing experience.

Is that the last of the slides there, Dave?

I know that's kind of a little bit jerky on the run-through and just the screen-shot model; we do actually have a machine running these applications. Those of you who may be interested can come by and talk to us afterwards so we can show you a little more detail if you're curious about how this product works in more detail.

So why don't we open the floor and take some questions? Yes, sir.

M: I have a couple questions. How do you charge for your product? On a transaction basis?

David Bernstein: Yes. The question was, how does EPR charge for our technology? We're a middleware company, so we're supplying this company to partners who are integrating it into their on-line service and Internet products. What we expect will be the model will be the normal Internet model, and that is that the authoring tools and the client-side tools will have no charge associated with them, and EPR and its partners will make money as content actually flows through the system. And so yes, that will be a transactional model.

Question in the back. That's you.

M: You mentioned that there were some standards activities going on this year. Could you talk a little bit about who's doing what standards work?

David Bernstein: The question was, "Who's doing what standards work?" Dave, do you want to —?

David Van Wie: Yes. Actually, there will be a meeting a little later on today, I believe, over at the Swiss Hotel, that's being sponsored by the IIA, and they're putting together a new group. I believe it's called the Electronics Rights Management Group, which has representatives from major companies as well as people who are providing services, and then ourselves, the ones providing technology in this space.

M: Can you give us some names of companies [inaudible]?

David Bernstein: Wait for the announcement.

David Van Wie: The announcement will be made a little later on today, so I don't want to pre-announce who will participate in that activity, but certainly many major providers.

M: What's the pricing on these cards? And are they all in the chain you talked about? Where do your products come in, and how much do you charge for them?

David Bernstein: Repeat the question.

David Van Wie: Okay. The question was, "Where in the value chain do our products come in and how do we charge for them?"

Let me just summarize real quickly again what the pieces are. We provide a user application for packaging content, a Digibox packaging application. We provide a rights editor that lets you describe using the graphical tools I had up just briefly and lets you describe the business rules associated with your content. We also provide a tool for taking Digiboxes and automatically building Web pages from them, and then we provide the system software that integrates into your system so that you can allow *Netscape* to run more or less transparently with protective content. And then, finally, we provide a clearinghouse application.

Now, as Dave indicated, the ordinary Internet model is one that we find very attractive, which is that the authoring tools and the *Netscape* integration will be provided for free. And then EPR and our partners will participate in the transaction flows that are caused by content. So that would include the whole intermediate value chain.

Yes, sir.

M: As author or publisher, one side puts my content in your container and it moves out, and a user decides to just take part of that; how do I determine what part I want taken, what part I don't, or do I have to make it total?

David Van Wie: The question was, "Once something is inside of a secured container, can authors or publishers determine which portions of it a person can extract and describe the business rules that would be associated with that?"

And the answer is that using the *NetTrust* model, yes, you can describe that. And part of the authoring process that we didn't go into would involve describing the pieces of the content that you would permit to be extracted, including the granularity and so forth. And then those represent a special category of events just like the open I was showing a moment ago that you can just completely describe business rules for.

Yes, sir.

M: Having to distribute a database like that for the use of information, are you assuming a live connection at the time of payment or do you have some kind of facility for deferred payment and accumulation of usage data as a bolt or a fast job?

David Van Wie: The question was, "Do we require some kind of live connection or are we able to aggregate transactions and then send them through as a batch, if you will?"

And the answer to that is also yes. We can do it either way, actually. Some transactions are sufficiently high value, and some business models will require that you form an on-line connection to fulfill the payment part of the transaction. We provide technology that lets you aggregate transactions locally in a secure way and then transmit those periodically to a clearinghouse or to a publisher, whomever is going to take on the responsibility of actually clearing those and getting the bills paid.

M: Can you describe the difference in your business model from other metering companies like InfoSafe and Wave?

David Bernstein: Do you want me to take this one?

David Van Wie: Yeah, why don't you take this one.

David Bernstein: The question was, "Can we describe how our business model differs from other metering companies such as InfoSafe and Wave?"

Without speaking for what their particular business model is, I can tell you that we are a middleware company, although our implementation works in a software-only mode, or with secured hardware such as a smart card or other pieces. We do not sell a piece of hardware; we have partnerships to do that. And although we have reference implementations of clearinghouse software, we are not a clearinghouse. We have clearinghouse partners.

So in those two aspects, there have been differences in our approach with other companies in that we are purely a provider of technology, and software technology at that, and not a provider of a piece of hardware or a clearinghouse. There will be multiple clearinghouses for people to choose from, and multiple implementations, those that are software only, those with hardware and with a variety of pieces of hardware. And so to that extent I think we differ from those models. We think multiple clearinghouses and multiple models of security, hardware, software and so on will emerge over time and we'll support a lot of them.

Continuing on your previous question, I'm sure. New question.

M: Well, I'm here wearing several hats, and some of the interests I'm representing, so to speak, don't give a damn about payment. They're in the business of distributing information at no charge. However, they're very concerned about the integrity of information they distribute. They don't [want it taken] out of context. We don't [want to] see it modified.

From the presentation you've given me, I feel real good about the data until it gets into some kind of application. What I'm saying is, it looks to me like their castle is reopened, but I'm having trouble understanding, until third-party application developers respect your business rules, how today a Netscape user is going to read the text of my customers without being able to copy it?

David Van Wie: The EPR has not invented an anti-gravity machine. Let me repeat the question here. The notion is, how is it, without third-party developers adopting this model, such that we have the system out there broadly, and well integrated...

M: We're out of time.

David Van Wie: Are we out of time? Well, I'll be quick. You can, if you deliver this directly back into *Netscape*, copy it and save it, and existing copies of I.X models of *Netscape*. In future versions of *Netscape* they've promised us all that they're going to give us an API that lets us control the user interface, and that will allow us to improve our existing helper application such that it can go ahead and control printing.

For example, you may enable it, but send a signal down into the protective processing environment to record how often that's done and perform the charges and so on. That speaks to one aspect of it.

I should mention that our existing helper application today has a full user interface for text and graphics and movies and so forth. So rather than handing it straight back into *Netscape* for the most transparent model, a publisher can choose to have it land inside of our helper application, where we do have full control over how these things can be done.

Now let me make another point. We also use watermarking, or what we call "fingerprinting" techniques. As your content is released you do have the ability to keep track of who released it, when they released it, which machine it was on and so forth. This provides a relatively powerful disincentive to copying.

Let me make a final point with respect to integrity. We don't have to associate charges with any of the activities; in fact, you can ship out your content either for free or on a subscription basis, and if you simply inform the customer base that if it arrives in a Digibox, you know it has integrity. Therefore, if they receive it in the clear, it's not inside of a Digibox, it's suspect. And it's certainly a transparent model, so if there was no charge associated with it they would see nothing except an indication that it had been received with integrity.

M: What platforms...

David Bernstein: Let me close it up. Okay. Final question — what platforms? All the various Windows platforms today, Mac and Netware tomorrow, in the figurative sense, of course.

I think we're out of time. Thanks for the good questions. You'll see on the screen here the requisite Home Page for EPR, www.epr.com. Visit us if you'd like more information, and don't hesitate to come up and chat with us. There is a panel in the next session with several experts in the digital copyright area for those who have additional interests in this hot topic.

Thanks for coming today.

PUBLISHING ON THE INTERNET COPYRIGHT: A PANEL/AUDIENCE INTERCHANGE

MODERATOR

Dave Bernstein

Vice President, Marketing, Electronic Publishing Resources

SPEAKERS

David Van Wie

Chief Technical Officer, Electronic Publishing Resources, Inc.

Eamon Fennessy

Chairman & CEO, The Copyright Group

Kelly Frey

Director of Business Development, The Copyright Clearance Center

Arthur Hutchinson

Senior Consultant/Principal, Northeast Consulting Resources, Inc.

Dave Bernstein: Thanks for suffering through our bit of disorganization here as we get a little overwhelmed with questions from the last session. I guess that's a good thing.

This is session G-2, a discussion on electronic copyrights and I'm pleased to say we have a panel of distinguished experts in the area, who will each give a five minute or so presentation on some of the issues, each from differing perspectives. I myself, Dave Bernstein, V.P. of Product Marketing from Electronic Publishing Resources will moderate the panel.

I'd like to introduce some of my colleagues. David Van Wie here, Chief Technical Officer from EPR, will be on hand for questions at the end and so on. Our first speaker will be Eamon Fennessy from The Copyright Group. He's Chairman and CEO. They are based out here in Massachusetts. Kelly Frey on my right, is Director of Business Development for The Copyright Clearance Center, who are based out in Danvers, here also in Massachusetts. And Art Hutchinson, who's a Senior Consultant at Northeast Consulting Resources. He is one of the leading analysts and consultant in the electronic commerce area, and a specialist in something you might have heard of as "future mapping". So that, I think will be an interesting set of speakers and we'll talk briefly about all the issues about copyright in cyberspace.

Kelly, if you wouldn't mind just clicking once over there. For those of you who missed the last session, the whole issue of copyright in cyberspace, comes about because digital content is what we're talking about, where digital information is the product. We're no longer talking about ordering CD's or videotapes and receiving them over the Net or receiving them in the mail. We're talking about distribution of digital information over the Net and publishing scenarios of business information, interactive media, software and entertainment products, delivered digitally over the Net or on digital media such as CD-ROM's and so on.

Clearly, the Internet is a hot topic, but this is an identical problem when you talk about CD-ROM media, satellite TV or cable, when you talk about private networks, such as some of the large on-line service providers, and combinations thereof, where media, where the digital product comes both over the Net and on a CD – something to that effect.

Information commerce, as we've defined it in the earlier session, is a case where we have digital content and there's a way to pay for it. We've enabled some kind of value chain where there are authors, there are distributors, there are multiple rights holders in this scenario, and there's marketing and usage information.

Now what we're going to talk about here is this first bullet item, extensively on protection of copyrights here, because digital products are copyrighted, and we'd all like to

enable the protection of copyrights in cyberspace, so that we truly enable an information commerce industry on the Net.

Okay, then our first speaker in this area will be Eamon Fennessy.
Do you need help with the overheads then?

Eamon Fennessy: All set. Good morning. The Copyright Group is a group that's up the north shore of Massachusetts and what we are are copyright agents. We arrange permissions for people to use copyrighted materials electronically, also translations and other derivative rights.

If I can have that first transparency please.

All of this goes back to the Constitution. And this is going to be pretty basic, but what I'm more interested in with you folks is to let you know what copyright is and then see if we can answer some of the questions that you have applying the copyright law to digital technology and digital commerce.

The forefathers had the foresight to say creations, whether it's a sculpture or imprint or what have you, and inventions, belong to the authors, the creators, for an exclusive period of time. And that's the basics for our copyright law.

The second one please.

While he's putting that up, I'd like to refer to copyright as a bundle of rights. It isn't just the right of reproduction. Reproduction is the first one. But there are also other rights that everybody, whether you're an author or a publisher or a vendor, if you're using materials created by someone else, or being an author, you're willing to license your works to others. You should be aware that there are several rights included in copyright. Reproduction is one.

Derivative works. I mentioned translations, videos, films – films that were based on books – those are all derivative rights, and they belong to the first creator unless they are licensed to someone else.

Third is distribution. That is the right of the copyright holder, himself or herself. And in writing contracts, in writing agreements to license your works, you should be aware of these, and make sure that if you are an author or creator, that compensation is included in that agreement, identifying the specific right that you're licensing.

Fourth is to perform it publicly, and that usually applies to music. It could apply to reading poetry and things like that as well, but that is another part of the copyright.

And the final one is to display publicly. No one can take your work, put it onto the Web without getting your permission.

So I'd like you to keep each of those specific rights in mind, whether you're a vendor, a publisher or an author, because they are valuable pieces of intellectual property, and they belong to you until you assign them away.

I gave a talk in Baltimore on Friday to the Medical Writer's Association, and one of the key points that I stressed with them, is that they should not be selling their rights, they should be licensing the rights. That is, you're giving it to someone for a specific period of time, or for a specific period. First publication rights in North America, for instance, or electronic rights to put it on a CD. But you simply don't sign away your copyright with phrases like "in any form" or "in any technology hereafter to be discovered" or anything like that.

A little story. Back in the 30's there were two high school students name Segal and Schuster. They came up with a cartoon. They sold it in the 30's for a \$130, all the rights to it. And they thought it was terrific. High school kids, \$130 in the depression. The cartoon was Superman, and if they had known what was happening to Superman in the 30's they would have changed their tune I think. But anyway, the rights holder was giving them a fair deal, they enjoyed it and they got the rights that they wanted and the high school students got a \$130 bucks.

Last item is fair use.

Next slide please.

A lot of people feel that they can use someone else's work and just say that it's, "Oh, it's all fair use." And fair use is provided in the copyright law. But when you consider fair use, you really have to take into consideration these issues. There have been several well-known cases: Texaco case, Kinko case, where people have used other people's copyrighted works and using as a defense, fair use. But if you're a commercial firm, take a look at that very issue there about the purpose and character of the work, the nature of the work, the amount and substantiality of the work. You certainly cannot consider fair use and take somebody's entire journal or entire article.

And then the last issue is the effect that your use has on the market for it.

Those are really what I consider the basics of copyright. They were originally set up for print, but they are certainly in the electronic sphere.

I see a hand here.

David Bernstein: Questions at the end please.

Eamon Fennessy: Oh, he wants to have questions at the end, but please don't forget whatever your question is. Um, that's it in a nutshell. Those are the basics of copyright. You have to whether you're a seller or a licensee, be aware of the issues of copyright in the electronic medium. And I'm looking forward to your questions. Thank you.

David Bernstein: Thanks Eamon. I guess we'll need that right-hand screen or projector here again. Okay. Our next speaker, Kelly Frey, Director of Business Development from Copyright Clearance Center. And Kelly, I'm happy to drive that for you while you talk.

Kelly Frey: Thanks. Is there a mic that I can [inaudible]?

David Bernstein: I don't know if there is. It's kind of attached.

Kelly Frey:: Is it kind of attached or...

David Bernstein: It's kind of attached. Why don't you, why don't you come over here and stand at the podium.

Kelly Frey: In the digital world you have to move quickly and so the presentation I prepared last night changed. And I like the comfort of sitting behind the monitor.

Copyright Clearance Center is a U.S. Reproduction Rights Organization. If you can go onto the next slide. We'll go through these quickly. Just to give you an idea where I'm coming from as far as copyright is concerned, we're really the interface between information providers and information users. We're a non-profit trusted neutral party. We represent some 9200 publishers and hundreds of thousands of authors across the world. We license the works of those individuals to some 6200 companies in the United States, including 80% of the Fortune 100. We've had about fifteen years worth of rights management experience. So copyright is our very existence. And the management of the copyright, being able to commercially exploit those rights is what we do for a living.

Next slide please.

A couple of specific interests that our company has. We have an electronic access program. And this is looked at as an immediate solution to a real problem. You have a vast

collection of print material that's out there now. There are no digital rights associated with those materials. What we're trying to do with our digital access right is create a simple scan, store and transmit license, that would allow corporations on their local area networks to take bound items that they have now, and just convert them to digital form. That's not something they can legally do. They need a license for it, so that's what our company is beginning with.

It's a first step. It really allows the type of business usage that you see going on now. So what we're trying to do is legitimize an activity that occurs now. Coincidentally, there's probably some royalty payments that are owed for the use of those proprietary materials and we'll be involved in collecting and distributing those royalties.

We have more general digital commerce interests however. And our interests are not so much involved with what the law is, because the law is changing. What we're interested in is how to use the law to facilitate an effective digital commerce in information. We're looking for supporting technologies that will provide market solutions to the real problems that we have in the copyright arena now. We want to make sure that creators' works are protected, but we also want to make sure that the rights of the users are protected. That they get full use of their fair use advantage, that they have ready availability of very high value content, and also that their privacy and confidentiality interests are protected as well.

We do want everyone to recognize that just because you're in a digital environment, doesn't mean that the U.S. copyright law goes away. This is a very difficult concept for people to get across because in fact, it's so easy to scan something. It's so easy to clip something and put it in an e-mail and send it down the hall. The technology has allowed things which legally are not permissible.

So we need to create situations that will protect the content while making sure that you have the availability of usage of the content.

We're also looking at the availability of technology to implement the various business models that are being created. We've had a print, published paradigm for a long time. We're seeing a transition into digital publishing. But we have to remember that there are economic incentives available to those people who create new works. It's not just a matter of selling technology. We have to blend the technology with the specific content, and the needs of the users in order to create an effective marketplace.

And last of all, we've got a real concern for users of digital materials. While digital access allows many more options than what you have in print, it also allows many more abuses. And you may have seen, if you subscribe to EduCom or their newsletter, a recent blip about a UseNet group tracking postings that are made on UseNet. So in fact, there's availability if you participate in a UseNet group to now go back and actually track every posting that you made to that newsgroup. So we're concerned that those types of information stay within certain bounds, and they're not made freely available, so the privacy rights of the individuals are maintained.

So again, that's more or less where we're coming from. We're very committed to protection of materials using the current copyright laws where there are misunderstandings or where there's confusion, with respect to how the copyright statutes are applied. We would like to look at contract issues that would allow us to resolve those. We're also looking at technology, as being an enabling experience. It's not a restrictive experience. It's not a matter of just protecting content. It's a matter of making sure that content is broadly available to a wide audience.

So I'm looking forward to your questions too, but that's just to give you a background on where our interests lie.

David Bernstein: Okay. Great. Thanks Kelly.

Next speaker, Art Hutchinson from Northeast Consulting Resources.

Art Hutchinson: What I want to do in the next few minutes is outline broader context for how to understand rights management.

Next slide please.

One of the things we do at Northeast Consulting is a version of scenario planning we call “future mapping”. And one of the assumptions that we go by is that the future is inherently unforecastable, but that one of the ways to help understand events as they’re unfolding is to define some extremes.

In this case, what I want to do is define some extremes I call “end-states”. You can think of them as business models for how publishers make money in cyberspace.

Next slide please.

Publishing is inherently a complex and messy environment, and there’s a tendency, particularly in the context of the Web, to think of publishing as being print, but you have to keep in mind that there really are four very, very different parts of the publishing industry, all of which have different assumptions about the way to make money, and different assumptions about their business models. I’m talking about software, print publishing, movies and recording music.

So again, think of these as business models. In essence, the pipes, the networks through which content is going to be distributed – don’t care. Digits are digits. What differs, are the people who are doing the publishing, and their assumptions about how to make money underneath that.

Next slide please.

So rather than starting with the four different business models that already exist in those four different publishing industries, another way to think about this, is that there really are two schools of thought as to how you make money off of intellectual value.

One is that, which is, I think an assumption, again, when thinking about the Web, is that the value resides in an object, in some kind of work. And to go to the example of the Superman comic a moment ago, I think an assumption there on the part of people who are publishing, is that there is some long-term value that you might be able to get out of that.

The other extreme is well, the value, it doesn’t really reside in a work, it resides in an interaction. People preparing your taxes. Certainly, the Grateful Dead believe that people will come to concerts over and over and over again, because they’re each unique experiences.

The next slide please.

And the other way to think about this is that there are two different extremes in terms of the bundling of things that are published. On one extreme, you subscribe to a magazine. There may only be a couple articles over the course of a year that you like, or certainly when I was growing up, I used to buy singles a lot. It’s hard to find singles now. You tend to buy albums. The public music industry, tends to force you to buy albums. It’s harder to find singles. On the other end, there’s the promise and some of the technology that EPR is talking about, certainly holds the promise of allowing content to be “desegregated” into smaller and smaller pieces, and still assuring publishers that they’ll be paid for those pieces. This scares a lot of publishers to death. Taking apart works and allowing re-use is a messy and difficult thing to think about when you’re not sure that you’re going to get paid for all those pieces. And it’s one of the things holding back the multimedia development industry right now.

It’s also one of the issues that the software is wrestling with. Big, complex packages of software, that have all kinds of features that you don’t need. And the object-oriented world, certainly is thinking about the ability in the future to be able to see individual objects.

Next slide please.

When you put these two together, these two spectra together, these are really what I think of as four different end-states or business models for publishing. Time, you think of as a metered interaction with a person. Admission, you can think of as access to an event. How many people got in here without getting past the people in the green shirts today? And you can think of those as protecting a channel, a channel of communication. You're not sure what that channel is going to hold once you get in, but the protection is of the channel.

On the other side, subscription is about access to a work. Here, you're protecting an object. And then usage is about protecting a small work, a piece of a work. Now this is the hard part. This is what hasn't been achieved yet on the Internet, but which is being enabled by some of the technologies that are being released today. EPR is one of them.

Next slide.

The problem with lighting these conceptually neat packages and business models, is that you immediately start to think of exceptions. You go into an art gallery, well, you're charged admission, but those are works, they're fixed works. Time-based chat room fees, the Deja News that was just referred to is keeping track of all these Internet postings. Well, you thought you were having access to an event, a chat event, but really your chat is now recorded, it's a permanent work. So there's a lot of exceptions here.

And then the final one talks about the fact that you can't cut up works very easily today. Next slide please.

So the business model for charging for time, one of the most important assumptions here, is that information objects are advertisements for an interaction. You'll see attorneys out on the Net who are releasing little white papers about some particular niche issue that, well, it gets them fees. And so the way some people think about making money through publishing, is not through publishing itself, but through generating professional services fees. Consultants and lawyers and accountants make money this way.

Next please.

So some of the milestones or indicators that might say we're moving towards a world like this, that there is starting to be more free information on-line – that there is starting to be more spamming out on the Internet – those are really just advertisements for interacting with a person. The use of 900 numbers might increase dramatically. So these are some things that if, if you saw these things happening, it might be saying we're moving towards a world in which the business model was more charging by time.

Next slide please.

So most people don't think about either time or admission as being legitimate business models on the Net, but you can certainly imagine all kinds of fee-for-service applications on the Net where encryption is used not to protect an object, but to protect a channel, or to validate a person's identity, allowing them to have an interaction that's paid for over the Net.

So one of the assumptions under this kind of a business model is, "I'll release all kinds of static works." You can have plenty of copies of this presentation, but what's the valuable part is interacting one on one to work with you on some problem or a private performance, for example.

Next slide please.

So some indicators that might in the future say the world is moving this direction – I like to call this the John Parry Barlow end-state, you know, that bootlegging and copying is encouraged, because then you'll come to the concert. You'll want to experience the real event.

So next slide please.

So the two end-states, the business models that I think are most interesting right now, in terms of publishing on the Internet have to do with subscription and usage. And subscription is really a huge bucket. I don't just mean subscription here, but everything from books to

magazines to albums. Anything where physical protection is the main means of copyright protection. People think that they're buying an object, and what they're really buying is the right to use that property, but it's physically protected on a CD or in a piece of paper.

And the assumption here is a dangerous one on the Internet, that the stuff – there's a little bit of copying we'll charge to allow for that, but that copying is never going to be enough to destroy the business. Well, that changes as soon as you get out on the Net, regardless of the legal restrictions. I routinely receive anonymous re-mailer messages on various newsgroups I subscribe to that are postings of articles that appeared in major magazines. Anonymous re-mailers on the Internet certainly poke a hole in that, and again, it scares to death the publishers. There's a tremendous volume of content that's out there. Various estimates put it around an order of magnitude – you just count bits, you count terabits. An order of magnitude difference in the amount of stuff that's out on the Web now, versus the amount of stuff that's in the databases of folks like Lexis-Nexis or West Publishing or folks like that. So the problem here is that you can release this stuff on the Net and get paid for it.

Next slide please.

So some indicators that we're stuck in a subscription world, or we're moving more towards a subscription world would be, that traditional publishers continue to thrive. There is no disintermediation, that the flood gates of content don't open and go out on the Net, that there continues to be a tax on blank tapes, for example. The legal emphasis remains on physical objects. And that softer products and music and all kinds of content remain very much bundled. You can't buy just the word processor core. You have to buy the whole thing.

Next slide please.

So finally, usage, and this is where the term, the dreaded term "metering" sometimes come in. This is the promise of being able to protect and dictate the terms for an object, however small that object may be, be it a sentence or a song or a piece of a song. And one of the things that people forget when they hear the term metering and start thinking about usage, is stuff that's free now doesn't necessarily have to not be free if you protect your rights to it. That you can put things in digital envelopes, encrypted digital envelopes and dictate the terms for those without necessarily having to charge for them.

One of the assumptions in having this end-state occur is that there have to be standards for this. Think of this as envelopes for digital content, in the same sense that we have standards for having stamps in the upper right-hand corner, and return addresses in the upper left-hand corner today in the physical world.

Next slide please.

Some indicators if we are moving towards this world would be that the flood gates open. There's an increase by an order of magnitude or so in the amount of content that you can find out on the Net because objects would be encrypted. You don't have to worry about protecting the channel. You don't have to worry about protecting access anymore. It enables something – the term super distribution – that you don't care anymore about protecting who gets your work, because once they've got it, they still have to open an envelope and agree to terms and pay for it.

Next slide please.

To summarize, some of the keys differences between subscription and usage is that moving from a subscription world to a usage-based world, means moving from legal protection of copyright to technological protection of copyright. No longer do you have to worry about whether somebody is doing the right thing, and whether they're moral enough to not use an anonymous re-mailer. The object itself is protected.

And we're also moving from physical protection to virtual protection. You're protecting software, protecting an object, a digital object, rather than protecting a warehouse full of videotapes, or a warehouse full of floppy disks.

The other thing that's interesting, certainly extremely interesting to publishers, is the difference between these two worlds, the potential for feedback.

In a subscription world you know as a publisher that x-number of people bought the March issue of your publication. The promise of usage-based measurement metering is that you might know that this article, this particular article was read by this particular person on this particular day for this number of minutes. Well, that's scary. That's really scary. But there are some ways short of that, that publishers can get a tremendous, tremendously richer stream of information about how their content is being used, such as you know at least that this particular article was the most popular article in that magazine because it was read by x-number of people. So you can start as a publisher, one of the things this enables as a publisher, is to get feedback about what content is working, what content is not working, and to tune your creation of new content to the needs of your marketplace.

Um, the other thing to understand about the difference between these two business models, these two end-states is that in the subscription model, relationships are very formal. Distribution relationships are formal. Distribution channels are inherently constricted. Whereas, as I said earlier under super distribution, the promise certainly is to have an infinite channel. People put things up on the Net and they succeed or fail on their merits. People send things to their friends. It's the classic case of the comic strip producer that was mentioned earlier, who puts their content up on the Net and people download it and pay a nickel for it every day, and they develop a following.

Next slide please.

So one question you could ask would be, "So how are these four publishing segments going to evolve in the future?" Um, but that's an easy question because it's already fairly clear how some of them already are evolving, that software is evolving more towards a usage model, or more quickly anyway, and that film and recording, well, they kind of straddle a subscription and an admission model.

Next slide please.

So I would say the better question to ask is, "How do these different business models come together in the future?" Because one of the things to understand about the technology's underlying usage metering, is that if you can meter at a very granular level, if you can protect content at a very granular level, you can always aggregate up. You can always simulate a subscription model. You can always simulate all of the other business models, but you can't go the other way.

So metering is about creating a richer range of protection and payment mechanisms for a variety of different publishing industries, and it will be interesting to see how it evolves. Thanks.

David Bernstein: Okay. I think we've heard from our speakers, and maybe if we can bring some lights up. As promised, we want to make available this panel of experts to you for questions. So let's get some lights perhaps if somebody knows how to do that. And we'll take questions in the dark for a while. The front? Second row? Yes, you.

W: I was curious about how, I don't know if they're called primitive works or not, but things like parody and secure hold, things were covered under copyright laws.

David Bernstein: Okay. The question is, "How are satirical works, parodies covered under copyright laws?" And by the way, if you have a particular panel member you'd like to address your question to, please don't hesitate. Anyone want to try that?

Eamon Fennessy: As a matter of fact, can you hear me? The issue of parody came up, oh, within the last six months in a group called, I think, Capitol Steps down in Washington, who parodied so many popular tunes and of course, directed towards the Capitol and to the legislature and to the rest of it, but there have been other instances where people have parodied, parodied well-known tunes, put their own words to it and it's always been thought that that was strictly illegal. But the most recent cases have filed that, "No, as long as it's, whether it's educational or just entertainment or however the courts decided." That really has been a blow to the rights holder, that people can parody things and get away with it. That refers to the performance of copyright issues.

Kelly Frey: One other thing to note that a lot of times, people are concerned with whether a parody replaces the original works. For example, in the recent Supreme Court case were it involved a 2 Live Crew and Pretty Woman parody, you know, the court basically said, "Look, there's not a big audience between the same people who would buy the rap music and would buy, you know Roy Orbison." So it's really not replacing the market that was originally intended to. So it was very heavily fact-based.

David Bernstein: The front here.

M: Yeah, it's a question about something that was brought up by a couple of panel members with the UseNet history. Um, so to make the question make sense, I'm going to give you my basic understanding. You tell me if I'm right or wrong. It has to do with, we learned about the rights of copyright, but we didn't hear about what the copyright holder has to do to ensure retaining those rights, protection of those rights. And a lot of the confusion about copyright on the Internet, I believe, comes from the fact that one of the basic tenants of copyright, as I understand it, is that you have to make an effort, a concerted effort to protect those rights and not allow anyone to use them. If you don't make that effort, then you're considered to have released your works in the public domain. And since distribution on the Internet necessarily, well, until the Well, even with WorldWide Web, since distribution on the Internet necessarily involves releasing your work to be copied on an ad hoc basis among multitude of machines, the electronic equivalent of putting out ten or twenty thousand paper documents without taking proper steps to ensure who's going to use them and how they're going to use them, that you might in fact, be relinquishing your rights by doing so.

David Bernstein: Okay. Let me try and summarize for the audio tape here. The question was, do you need to do anything special to retain copyrights, and because that's really hard to do on the Internet now, are you essentially forfeiting your copyrights by releasing content on the Internet? Anyone, any panelists like to... Eamon?

Eamon Fennessy: Yeah. With regard to anything you have to do to protect your copyright, the copyright law is that from creation you have a copyright that lasts fifty years beyond the death of the author. Fifty years is a long time. In the European Union, it's seventy years, and there's been legislation introduced in this country that will make our copyright also seventy years. That's not moving right now. So there isn't anything you really have to do to protect that

copyright except, if you see somebody really abusing your copyright and infringing on it and making money from it, sue them. Maybe Kelly, do you have anything to say about that?

Kelly Frey: Well, yeah. It's very important to note that you don't have to do anything in order to establish your copyright in the United States. All you have to do is create something. And as Eamon said, from the moment of creation, it's protected. Now there's some other things you can do. You can register your copyrighted work with the copyright office, and that provides you with some additional remedies under the federal statute. You can sue in a federal court. Your copyright registration is [prima facie] evidence of your ownership. You get statutory damages. You don't have to prove that you've been damaged. There's a minimum \$500 statutory damage if you go ahead and register your work. So there are some advantages. But as Eamon said, the critical point is, okay, so somebody's copied your work. Now what are you going to do about it? Our judicial system is really based on trial by combat. You know, if you've been offended, you've got to assert your rights in a civil sense, so you have to file a law suit. If you don't, nothing happens. The government's not going to take the place of you as an individual civil complaintant who's got some sort of injury, as a result of somebody else using your work.

David Bernstein: But the question was, even if you don't do anything, you still have your copyright?

Kelly Frey: Sure.

David Bernstein: Okay.

M: There's no precedence established by letting one person infringe, and then you decide to pursue a second person. If the second person can't say, "Since you let the first person [inaudible] pursuing them," I have in fact a right?"

Kelly Frey: There's nothing under the statute like that, but there are all sorts of common law defenses. And let's remember, the copyright statute says you may not copy period, right. And then it lists all these exceptions. Fair use is an exception. And it also has some defenses as well. And there are common law defenses. Latch is a common law defense. If you wait too long to assert your right, you lose it. All right? But that doesn't have anything to do with the copyright. It's the same thing is, if you ran into somebody with your car, if you don't sue them within a reasonable amount of time, you lose the ability to do that.

Art Hutchinson: But I think one of the other things that's an issue here, is that it would have to be a pretty valuable UseNet posting to motivate somebody to go through all this legal process to recover their rights. And I think what's at issue here is not that there are not legal and moral systems in place to protect this, but that the technological means for protecting this without having to incur heavy costs, are not yet in place. They will be coming into place. But for the moment, there's tremendous confusion when you go to post to a UseNet as to "Am I engaging in a conversation or am I publishing?" Where's the line between publishing and speaking here?

David Van Wie: I'd like to add just a little bit to that. One of the key constraints in designing any kind of technical measures to help owners and rights holders enforce their copyrights, is to take into account a distributive model. When you're working in the Internet, it's very important to go ahead and map your technologies right onto the existing topology of the Internet so that you

have a real distributive model, rather than attempting to put in place a centralized scheme. So I think you brought up a very important constraint from a technological point of view.

M: The [inaudible] from The Copyright Clearance Center mentioned 9000 publishers and 6200 corporations with whom you deal. Super distribution [inaudible] whenever using that user might not be a publisher, certainly [inaudible]. You're going to have to revolutionize his business I assume.

David Bernstein: I'll try and re-phrase that question a little. The comment was that the CCC has 9000 publishers and many thousands of other participants in the copyright area. When we go to a super distribution where, or on the Internet, where, with the technology such as Digibox, everybody can become a publisher, essentially, or creator, how can we handle millions and millions of copyright holders? Well, I think your conclusion is correct. We will have to revolutionize the way that rights clearinghouses and so on work. And EPR, for example, has announced, in an relationship with CCC to do just that. So that's what's going to happen.

[Tape change]

Kelly Frey: It's incremental like every other type of business so, for example, while we have a current business, we're looking forward to participating in tomorrow's economy as well, and that may mean that publishers or authors have a responsibility too. Maybe they need to register, so we'd have a Web site now, and we're getting ready to say, "Okay, if you as an author want to register something, sign-on to our Web site and register it. And we'll represent your interests as well." But you're right, technology is going to have to take the place of the handshakes and the paper contracts that have been signed over the last two hundred years.

David Bernstein: I mean after all, there are millions and millions and millions of credit card users. There's no reason we can't have millions and millions and millions of copyright situations. Yes?

M: Isn't there a difference between publishing in discourse? Now when we're talking about UseNet, aren't we talking about people interacting with other people in dialog and shouldn't, shouldn't that be a... What's the difference if, if I'm a reporter, and I'm sitting in this room copying down quotes from any of you gentlemen and I put it in the newspaper, and someone tracking all of UseNet so that a reporter down the road could do the same thing?

David Bernstein: Let me try and re-phrase the question and start with a brief answer. Others can kick in. Question was, "Isn't there a difference between discourse and publishing?" I think of course, there is. The key issue here is if somebody wants to, to protect a property of theirs, that's currently really hard to do on the Internet. And I don't think the question was so much in the UseNet groups necessarily protecting discourse, but people were actually posting to UseNet groups, actual copyright works of papers that had been written. So I think sure there's a difference. And perhaps there's a difference in the law on discourse versus... If one of you could address the gentlemen's quotes or question of regarding his writing down our quotes and publishing them.

W: Well, usually copyright will not apply to ideas. In other words, if you have an idea about how to make your Home Page or something like that, it's not really protected until you put that into a hard copy, or put it on some medium. So if you have it on UseNet and you attribute

some ownership to that, you can very well try to enforce a copyright on it if it's your creation, but very difficult. I don't know what, what more to say.

Kelly Frey: I think it does demonstrate though a matter of convergence. We're not just talking about copyrights, and we're not just talking about print publishing. You know, we're talking now about maybe a media that has characteristics of print publishing, some characteristics of broadcast perhaps, some characteristics of newspaper publishing. And in fact, it's not only copyright, but their first amendment rights, their defamation rights potentially. I mean, I may not care if you copy down what I say, but if you attribute some scandalous remark to me during the presentation, I feel like I should have some right to come back and have some recourse against you. So, you know, there are a whole bundle of rights. Copyright's only one.

Art Hutchinson: I think one of the other issues, the thing that's at issue here is reputation versus creating a work. That a lot of people will create quote unquote "works" they post to the Net, and their sole interest is not protecting those works, but developing a following in whatever community they want to develop a following – associating good thinking with their name or good guitar playing, or whatever it may be – they're not interested in protecting the small things that they produce on the Net, but protecting their reputation and their name and getting people to follow them later on.

David Van Wie: Part of the sorts of rights protection technologies that Dave and I were talking about earlier in that realm, is strictly to protect the integrity of your works, which I think speaks directly to that reputation issue, so that even though you're not charging or any other economic variables, you do want to ensure that your work hasn't been modified or falsely attributed to you, which either of those could be significant enough to use these sorts of technologies.

David Bernstein: That's pretty important when it's financial data or stock quotes or business data, you want to make sure it's what it purports to be.

David Van Wie: That's right.

David Bernstein: So... In the front here?

M: Yeah, when you talked about how different companies are now tracking what you post on UseNet, and talked about copying various bits of quotes from UseNet, what about using UseNet as a creation in and of itself? I mean, suppose I go onto different UseNet groups and take chunks of chats and publish it as a book. Or as Hot Wired and the company I work for, Prodigy, which will sort of be doing, taking a derivative work and doing sort of like a Talk Soup type of thing, where you take different sort of portions of UseNet and you do sort of like a funny column about it or something. I mean, if you're creating something that you then copyright in and of yourself, either as a book or as a publication on the Net, can the people who originally posted those notes come back to you and say, "Well, I didn't give you permission to use my work in this way."

David Bernstein: Let me try and summarize again for the tape. The question was, "What's the implication if there's a chat or UseNet group or somebody posts a whole series of answers to facts, frequently asked questions, and then later on, somebody else summarizes, like a Prodigy or another service would, they'll go ahead and take that whole result of that chat or that whole

newsgroup, publish it as a separate on-line book, magazine or a print publication, what about the rights of the initial people? Could they come back and say, "Hey, I didn't give you permission." What are some of the implications there of the various contributors? Eamon?

Eamon Fennessy: Yeah, I think that really goes back to the slide that I had, the transparency on fair use. Are you going to charge for it? If you recall, the fair use was, the factors to consider in something like that if you're putting it together, what sounds like an anthology, the purpose and character of it, is it commercial or non-profit? The nature of the work? Well, it's available to a whole lot of people. That's probably not a problem. The amount and substantiality of that work? You have to consider these if you're going to put them together and take them from the Net. And then are you going to give them away? Is it going to be a charitable publishing endeavor, or are you going to charge for it? And then the effect of it, of that on the potential market. Probably the people whose works you're taking did not intend to sell it themselves, so that wouldn't be a consideration. But the fact that it is in a medium, which can be recognized, really makes it subject to the copyright and you have to consider that if you want to publish someone else's works.

David Bernstein: I'll tell you that, to give a relevant example. Those of us up here today all signed a release regarding our current participation in this conference, so that the people who put this conference on, could do exactly that, publish an anthology or conference proceedings as it's known. So I think you know, for those of us who do contribute a lot to things like this or on-line discussions, you know, we're used to signing releases. And I've actually done that in on-line conferences, when you join a conference that's you know, going to be, have a record and a transcript published, you in essence sign a release at the start. So you...

Art Hutchinson: There may in fact be a change in that power relationship though in the future that if you are able as an individual posting to a group to make very specific terms about how your posting can be used before you put it up, attaching those terms to a cryptographic envelope that surrounds your posting, well, that's very different than signing a release before and signing all your rights away. So that you might post something that says, "It can be used for any purpose except an anthology. And if it's an anthology, it's going to cost you x-dollars to open this up, or you must phone home to this provider to arrange payment."

Kelly Frey: And one more thing, let's not deal with this in the abstract. Let's deal with it practically how it's going to affect you. This is the question – "Do I have to do anything to protect my rights?" It's the cumulative liability. Over time, the more you do it, the more people you include, the more exposure that you get, the more likely you're going to have someone who's disgruntled because you're making money, and they're not, and you're using their material.

David Bernstein: Way in the back there. Thanks for your patience, keeping your arm up.

M: A lot of Web sites have directory areas and business sites which allow you to link directly into other sites. When you place those links into your site, are there any legal issues?

David Bernstein: Okay. The question was, "On Web pages, if you place links on your page, are there any legal issues associated with, with having those links on..."

M: Or permissions. It's seems it's pretty widespread [inaudible]. The precedent is there's no permissions needed.

David Bernstein: Do you need to have permission to link to somebody else's site? Anyone want to take a shot at that?

Art Hutchinson: I've just observed that in some of the companies we've worked with, that has been a hot topic of debate. On one end of the spectrum, a company's legal department was extremely fearful that they would be in effect, endorsing all the content on the other site, and that would lead to some kind of liability. At the other end of the spectrum, a biotech firm we were working with actually measured their marketing people on the number of hotlinks that they managed to put on a Web site in a certain period of time. That was their primary goal during that quarter was to get the number of links up to a large number. So I think it has more to do with corporate culture. I'm not sure I could speak to the legal question though.

Kelly Frey: One thing you might want to be careful of though is the defamation aspects. How many of you have surfed babes on the Web?

M: [inaudible]

Kelly Frey: Okay. All right. Excellent.

David Bernstein: Can we get a comment from you on that?

M: Oh, I...

David Bernstein: What was your question?

M: My question was actually going to tie into this. I really [inaudible]. I've had legal threats against me and every one of them have failed. And basically because there is no defamation on my site. And I think [inaudible], that if you have a link available on the Internet, you're requesting somebody to link towards you. I mean, you're making yourself freely available. To me it's the equivalent of bibliography intrigue or [inaudible], being able to reference someone else's work, as long as you are within that area, not defaming character [inaudible].

Kelly Frey: Right, yeah. Your links are names, but you know, if they said, "Here's a nice Nazi." You know, or...

M: Right. We don't say that. [inaudible]. Now that might be defamation of myself [inaudible] articles, but to no one else the data really is in violation of character. It might be in bad taste, or it might be in just moderate taste, but there's no legal aspect about it. It's been thoroughly researched by the American Bar Association and [inaudible]. My next question I have is...

David Bernstein: Okay.

M: Regarding, say I want to design a page that has all the comic strips on the Internet that change on a daily basis. I'm not going to store any of those documents on my server. I'm going to write a HTML file that says, "For view of browsers, refer to this different site and retrieve

that graphic.” Am I violating copyright in that situation? I’m not storing the image. I’m telling the browser to retrieve the image from a different server.

David Bernstein: Okay. The question, just to re-phrase for the tape was, “If I create a page that has links to a bunch of other comic strips which change on a daily basis, or other copyright, and those include graphics, am I violating any copyrights or other issues, even though I’m not storing any of the materials, just links?”

M: I’m making references.

David Bernstein: You’re making references. Anyone want to comment on that?

W: I would say that you’re probably all right. I can’t think of any reason that someone who has material on the Internet and you’re simply referring other people to that, I don’t think they’d complain at all.

M: Well, I’m basically requesting their browser to bring up that graphic, so I’m actually causing a mode of distribution for that image.

David Bernstein: Yeah, but...

M: But that image is coming from that source. Is that a violation from me to control their distribution?

Kelly Frey: I think your primary problem there is being a co-conspirator. You know, if you’re directing people to a site that actually has unlicensed copyrighted material and your...

M: This is from the original site.

Kelly Frey: Right. But I’m just saying, if you’re directing people to a site that has material, and you know that it’s unlicensed and it’s not that owner’s, and you’re selecting and getting a fee for that, you know, I think that there’s a good argument that could be made that you’re a co-conspirator and in a copyright violation.

M: But if I’m going say from United [inaudible], and I want to display that on my personal Home Page but also [inaudible] the image, I shouldn’t have a problem, correct?

Kelly Frey: I don’t see one.

M: I don’t see one.

M: [inaudible]. They put that comic strip on there so that people will come to their page and click on that ad, and then he sets up his page, grabs the comic strip, does not grab the ad?

David Bernstein: Okay. The question is, “Suppose the page with the comic strip had advertising in it, and the previous gentlemen’s link was directly to just the comic strip, just the sub-URL for example, then what’s the issue there?” Boy, now this is getting interesting.

Art Hutchinson: You're facing the same issue that broadcasting is facing right now. Do you put the ads between segments, or do you put the ads along the side of the screen? Is there a way to link the two together? Create permissions that surround the entire entity of the comic strip plus the ad? A lot of different ways to work that one.

David Bernstein: From EPR's perspective, you put the ad and the comic strip in the same container and there they stay. But... In the back there.

W: What constitutes new use of publishing material? [inaudible], you can essentially keep it there for three years if you want, but three years from the date that you [inaudible].

David Bernstein: I guess the question was, "What constitutes new use of material?" In summary, right? Someone have a shot at that.

Kelly Frey: You have all of the copyrights as soon as you create that material. You can license out certain portions of rights, either for a specific time or for a specific use, but you maintain the rights over time unless you give them away or sell them to someone else or license them to someone else.

David Bernstein: Okay. Well, unfortunately, I think we're even five minutes over our time, although there's still questions left. I think all of us will be around afterwards for some questions. Thanks so much for attending these lively topics on electronic publishing. Enjoy the rest of the show. Thanks.

PUBLISHING ON THE INTERNET ON-LINE NEWSPAPER SERVICES: WHERE THE INDUSTRY IS HEADING

MODERATOR
Walter Chavez
Web Developer, iWORLD

SPEAKER
Steve Outing
President, Planetary News, LLC

Walter Chavez: Good afternoon, ladies and gentlemen. My name is Walter Chavez. I am a Web Developer with iWORLD Mecklermedia's site on the Web, and it is a pleasure for me to welcome all of you this afternoon to our afternoon session on on-line publishing. [Our] speaker will be Steve Outing, President of Planetary News. Mr. Outing will be talking to us about "On-line Newspaper Services: Where The Industry Is Heading."

Mr. Outing is an on-line publishing consultant, and at the same time he writes a 5-day daily column which is available on-line. He'll develop on that a little bit, so without further ado, Mr. Outing.

Steve Outing: Hi, thanks very much for coming. As Walter mentioned, I am an on-line publishing consultant, kind of specializing in the newspaper industry. I have worked in the newspaper industry for about 16 years before getting interested in Internet stuff.

So, what I thought I would do is just tell you a little bit about the growth in the business, which has been pretty dramatic, especially in the last year. I'll probably spend a lot of time talking about revenue strategies that various publications are taking, and I'm going to talk a little bit about alliances, which you see a lot of.

I just want to start by giving you a brief overview of where we're at in the newspaper business in terms of on-line services. The statistics will show that publishers nowadays have quite a bit of companies on-line and especially on the Web, so this chart dates back to 1982. Back then there were about three newspapers that were experimenting with on-line services, all of them in the U.S. They were like simple BBS systems. In fact, the oldest one, The *Fort Worth Star Telegram*, is still operating as a BBS today, although it's making the transition to Web Service. So as you can see, the idea of on-line newspaper services never really caught on during the '80s. These were text-based systems, no graphics, very slow modems; so until the '90s it really wasn't much of a viable business.

Things finally started getting interesting for newspapers in about 1993, and I track all these numbers for *Editor and Publisher Magazine*, which is where they all come from. In 1993 there were about 20 newspapers with on-line services, and what we saw in that year was quite a few alliances with the major on-line services. The *Chicago Tribune*, for example, created a service with America Online.

Things really started to heat up in 1994, where by the end of that year there were about 100 newspapers either operating or developing services. What we saw that year was quite a few alliances with the on-line services, especially Prodigy. They signed up the Times Mirror chain, Media General, and Cox Newspaper chains. The plan, then, with all of those papers that logged on with Prodigy was to create services on the Prodigy "Legacy Platform." Today, what's happening is some of that is being scaled back, and a lot of those services are now going to the Web instead; some of them will be working at Prodigy, and some of them will be doing it on their own.

And then in 1994, of course, that was also was the year that the Web really came into public consciousness and newspapers started to realize that it was a pretty hot thing.

So on the last bar over here, showing 1995, the growth has been pretty phenomenal. It's grown more than fourfold just since the beginning of this year, from 100 at the beginning of the year to about 540 newspapers worldwide today that are operating some sort of on-line service. So the herd instinct worked in the newspaper publishing business.

I would expect that by the end of this year we'll probably have about 800 newspapers doing some sort of on-line service, and by the end of 1996 I wouldn't be at all surprised to see about 2,000. So the business is really sort of coming out of the experimental, infant stage into toddlerhood.

Where up until now a newspaper company might have just allowed, say, one of its papers to experiment on-line, what we're starting to see now is the newspaper chains putting all of their properties up. Knight-Ridder newspapers is a good example of that; they operate about 28 papers in the United States and they've funded several projects for a couple years now, like the *San Jose Mercury News*, that you're probably well acquainted with. They have a service on America Online and the Web that's been going on for a couple years, and they recently bought 50% of an Internet access provider, InfoNet, and so probably all of their papers will go up within the next year.

Another group, PAFET, which stands for Partners Affiliated For Exploring Technology, comprises six sort of medium-sized U.S. newspaper chains. They're working on strategies to get all of their papers on-line.

Those were some larger newspaper companies. Now, what we're starting to see both in the U.S. and in Europe are groups of community newspapers going on-line. In San Jose, California for example, there is a group called the Times Newspaper Group, and they've got all of their six little community papers that serve different neighborhoods of San Jose on-line.

This slide is Pioneer Press Newspapers in Chicago, and this just came out a couple of weeks ago. They put all 47 of their papers on-line.

Let's see... Overseas there's also a joint venture in Sweden that a little later this year will put about 53 of its newspapers on-line.

The point here is that it's justified in that chart that I just showed you that we're really going to see a lot of growth next year.

Now, I fully expect on-line services run by newspapers to kind of follow a similar track to what the industry did with audio text. This chart shows figures from the Kelsey Group Research Firm out of New Jersey, and it's just the North America market and its interactive services operated by newspapers. The bulk of these numbers are audio text, so on-line is still a small portion of that; probably the next audio text experience in the newspaper industry will give us a good idea of what to expect with on-line services.

With all these wildly optimistic growth charts that I've shown you, I also wanted to just point out that probably in 1996 we will start seeing more publishers either scale back or possibly even kill some of their earlier experiments, and we're starting to see that now. This was the *Utne Reader Magazine*, which just a couple of weeks ago announced that it was scaling back its on-line presence. And in the newspaper business, both the *Los Angeles Times* and the *Milwaukee Journal Sentinel* in the last few weeks also significantly cut back the staff that they've devoted to their on-line services.

The *L.A. Times*, for example, had built up a pretty hefty staff of about 44 people, and trimmed it by 50% just a couple of weeks ago; they're transferring that over to a strictly Web-based service.

In Milwaukee what they were able to do — they're still going to stick with Prodigy at least for the time being — but they were able to cut back from about 16 to 9 people primarily

because they were able to automate a lot of the tasks that had required a lot of labor. I expect to see more of this going on in the next year.

Oh, part of the reasons for the Milwaukee paper needing to cut back was that they only had, I think, about 1,400 subscribers to their service — which obviously is not enough to support a staff of 16 people.

So, obviously the on-line service business is pretty competitive, and I think we'll see a little bit more of this. But I still remain pretty optimistic that the trend is still going up.

In the newspaper business, they're starting to figure out that the Web is pretty significant. This chart goes back to 1994, to when I said there were about 100 newspapers doing some sort of activity, and about half of them were on the Web. About 35% were affiliations with the major on-line services, and then the balance were dial-up BBSs that would not be accessible via the Internet. Actually, if you looked at this chart in Europe you'd see that nearly all of the activity was on the Web, so the BBSs and commercial on-line services alliances tend to be a U.S. phenomenon.

Okay, so this next chart is what it looks like today, and clearly the Web is the dominant force in on-line newspaper publishing right now with about 84% accessible on the Web, 9% affiliations with the on-line services and then 7% dial-up BBSs. Now, what this chart doesn't show is that there is also quite a bit of overlap, so many of the newspapers that are operating on the on-line services will also have a Web site. That's pretty typical. *San Jose Mercury News*, for example, has been on AOL for a couple of years, and they also very early this year launched a Web site.

The *Atlanta Journal Constitution* is on Prodigy, but they're also doing some pretty ambitious work with some Web sites that are already up that will deal with the 1996 Summer Olympics.

The *Arizona Republic*, that's kind of interesting, they've got a few Web sites up already. They are one of the few newspapers this year that actually signed a deal with one of the major on-line services, and they will be on America Online a little bit later this year.

What you're seeing with those papers on Prodigy is that they all are slowly migrating over toward the Web, so their content will be accessible by anyone probably in another year or so. With all those newspapers on Prodigy, their content will be accessible on the Web, and not just to Prodigy subscribers. And as I'm sure you're hearing at other sessions here, that's sort of the trend for all of the on-line services — to open up to Web travelers.

On the BBS side, most newspaper BBS systems currently either offer or plan to offer WorldWide Web access to their customers. So, in effect, some newspaper BBS operators have become Internet service providers for their communities. We're not seeing a lot of those, but a few of them. Indeed, there are still a few newspaper BBSs operating out there that don't access the Web yet, but I don't think those are going to survive long-term.

Actually, a good example of this is the *Kansas City Star*, which since last year had been developing a proprietary BBS system. The original business plan was to launch it with just minimal Internet connectivity, probably just e-mail, and the idea was to add Web access a little bit down the road. What they discovered during beta testing was that wasn't nearly enough, and their users told them that in no uncertain terms; so what that newspaper is doing is that they just recently cut back their BBS development, lost a fair amount of development work and are now building a Web service.

I was going to talk a fair amount about revenue strategies that the different papers are taking, and one that seems to be gaining quite a bit of popularity is that newspapers are going into the Internet access business. I mentioned Knight-Ridder Newspapers and their partnership with InfoNet in Virginia; the *Philadelphia Enquirer* and the *Miami News* will probably become Internet service providers in another year or so, and if you're in one of those communities

you'll be able to buy an access account. It will be like the Philadelphia Enquirer/InfoNet ISP, and they'll charge you probably \$20 a month for an account.

Some newspapers are doing that alone. An example of that is the *Arizona Daily Star* in Tucson. They've been operating as an ISP since May of this year, and they did the whole thing independently, which is fairly unusual. They currently have about 2,700 paying customers who pay \$20 a month, and that [monthly payment] gets them unlimited hours. So, they're actually doing pretty well. Their business plan was that they expected to have about 1,500 subscribers by the end of this year, so they're already well ahead of that; and they had projected that they would break even at about 3,000 to 3,500 subscribers.

As I said still, it remains to be seen whether a newspaper company can be successful with their newspaper-branded Internet access service when some of the giant competitors come along, and you've got U.S. West, Ameritech, AT&T, and some of the upstarts like At-Home offering Internet access accounts. What I tend to recommend to publishers is that they not try and go it alone, and they're better off allying with a provider like InfoNet that I just mentioned.

I'm watching closely the launch next spring of At-Home, which is a venture-capital funded cable television industry startup that is going to bring a 10-megabyte per second Internet access to American homes. I kind of wonder if a newspaper like the *Arizona Daily Star* is going to be able to match the challenge of something like At-Home.

I still will recommend to some publishers, depending on the market, that there are some opportunities in the access business, but it's not a universally-loved idea. A colleague of mine, [Rosalind Resnick], who is a fellow on-line publishing consultant, in her *Interactive Publishing Alert* newsletter in July wrote an editorial recommending that publishers definitely do not go into the ISP business. I just thought I would mention that if you're a publisher out there and you're thinking about this, to maybe get the other point of view.

I think the main thing that I wanted to talk about was the various ways that newspaper publishers are trying to make money on the Internet. My most frequently asked question is, "What publisher is making a buck on the Internet right now?" And it's really tough to find any examples of that, which is still just now coming out of their experimental stage.

So, let me just go through a list of various ways that a newspaper publisher can make some money on-line. As you'll see from this list there is certainly no shortage of strategies, but no one of these is really going to make you wildly successful.

The first one on my list, which we've just talked about, is ISP revenues.

Second will be subscription fees. An example of that is the San Jose Mercury Center. On their Web service the model is that anybody can see the sites free, but for the full content you have to pay a subscription fee; and if you subscribe to the print edition it's a dollar a month, and if you're not then it's five dollars a month. I think they've been moderately successful with that. They have, at last I heard, a few thousand people paying them.

Another revenue source is premium service fees. What you see a lot of them do is charge for access to newspaper archives, maybe like 50 cents a search or something like that.

Personal news clipping services. *San Jose News* has something called News Hound, which I think they charge \$10 a month for, and that will deliver articles from their various databases into your e-mail box. Actually, with the News Hound technology, you'll start seeing that on other on-line newspapers that are affiliated with Knight-Ridder or InfoNet.

Paper "click" content. I've heard that talked about at various other conferences here the last couple of days. You might want to charge, say, 50 cents just to view a certain report, or a few cents to access one of your databases that you have on-line.

Classified advertising. What I see a lot of papers do is they'll charge an extra dollar per line for a classified ad placed in the print edition, and that'll get you onto the Web site. I notice

this a lot with some of the smaller papers, where what they'll do is just raise the classified ad rates wholesale and then use that money to help fund the on-line service.

Enhanced classified advertising. Here a paper might charge an extra fee to put up a photo of a house, a photo of your car, that sort of thing. What you see a lot of them doing is offering deals to realtors, employment agencies or other dealers, and that gives the advertiser the opportunity to put their entire inventory of ads on-line rather than just a handful that would go on to the print edition.

Personal ads. The newspaper industry has been doing stuff with interactive personal ads for a long time, generally via voicemail-type stuff. Now they're all starting to port that stuff over to on-line. What they might do for a revenue source there is charge for enhanced ads, like charge if you want to put up your photograph, maybe a video clip or an audio clip of yourself talking, that sort of thing. This is kind of interesting. What I'm seeing is that some of them will set up a system where they will charge, say, 50 cents a message for two parties; once they find each other on one of these on-line personal ad systems, they'll charge for anonymous e-mail sort of as a safety measure. Once the two people who find each other in personals find that okay, maybe we want to exchange phone numbers, then the newspaper gets out of the loop and is no longer bringing in money.

Of course, advertising is where most publishers expect that they're going to make a lot of money on-line. I try to break this out into several different revenue streams; the first is just basically selling links to an advertiser's site, and the advertiser's site might be on a remote server or it might reside on the publisher's server. There are lots of opportunities for placing on-line ads in services like this. Obviously, with the news pages that they operate, a lot of newspapers have created niche services. We're seeing a whole bunch of golf services out there right now being done by newspapers, so that obviously is a nice little advertising vehicle.

We're seeing a lot of "event-centered" Web sites pop up. The Olympics, for example; I mentioned the Atlanta paper. Probably next year we'll see a bunch of those go up.

Topical Web sites. Some examples of that would be where one of the papers in Florida has a hurricane Web site that operates all through the storm season. Other sort of topical newspaper sites have popped up around major sports events, celebrated trials — I think there were a few O.J. sites out there — and this one is kind of interesting, we're starting to see a lot more newspapers put up community databases. So, this might be like putting a school test score database on-line, or putting up the local crime statistics and then allowing on-line users to find out the crime statistics on their block. So that also offers another sponsorship opportunity, like the school test scores that might be a good opportunity for, say, a realtor to sponsor.

That all came under the category of selling advertising space.

The second part of the advertising equation is actually hosting the on-line ads on your server, sort of renting service space to the advertiser so that you can get a separate fee for that.

The third component of the advertising thing would be to set up a Web site "construction and design" business. I'm starting to see more and more newspapers do that.

I should have kind of mentioned this before, but it's just the idea of selling sponsorship as opposed to just selling ads. An example of that was one of the Virginia papers, I think that was it, that sold sole sponsorship of sort of a temporary NCAA Tournament Web site, and sold that sponsorship to a muffler chain.

A few more revenue sources... One is software development. Some newspapers that have sort of done a lot Web development on their own developed their own software, and I'm now seeing them sell that to other publishers and other businesses to help them get on-line. Kind of related to that, I'm also starting to see some of them set up their own separate consulting services.

Running seminars. Some publishers are starting to host seminars for local business on how to publish on-line or to create your own Web site, or even just offer classes to the public on how to use the Internet. So, some papers you'll just see them offer these classes for free because, obviously, you're training new customers and that's good for you; but it's also a potential revenue source as well.

Transaction fees for on-line sales. If you host an on-line mall or an on-line ticket service, then you'll want to be keeping at least a small transaction fee or small share of the services. As an example of that, Bill Gates keeps about 5% of their transactions that take place via the Microsoft network.

I was up with their cellular subscriber list — and obviously there's some privacy issues that you have to deal with — but I am seeing a few people that are having some success with that, like the idea that a local sporting goods advertiser might be interested in the list of people who visited your golf site, for example.

The last one is that a lot of these niche services also offer some advertising revenue opportunities. If you have like the *Arizona Republic* does, if you've got a lodging guide and a golf guide, you can sell sort of enhanced listings. So, for example, if you go over one of these golf guides, you'll see all 50 golf courses in Arizona, and a couple of them that will pay extra will get either a video clip or a photograph and a listing, that sort of thing.

The point of going through that list is just that in this business there still really is no killer app, and no one of these things as yet is going to support your service. I generally recommend that you try and choose as many of these revenue sources as you can. Obviously, for a lot of papers advertising is going to be the bulk of it, just as in the print edition.

Probably a good example of this is NandoNet, which is in North Carolina. NandoNet is the on-line newspaper new media division of [Mechlache] Newspapers, and this originated at the *Raleigh News and Observer*. What they do there, they're an ISP, and they sell access accounts to the five county areas surrounding Raleigh. They have an on-line newspaper service called *Nando Times* and they sell advertising links on that, and those rates range from about \$2,400 a week down to \$38 a week. So, it just depends on placement and how often your ad is going to run. They also have some niche Web services.

For example, they have something called the Sports Service, sort of a national sports service and they sell advertising on that. They have a premium service, so generally their site is free, but if you want to pay \$12 a year — a pretty modest cost — then you also get access to all of their wires and could do searches, that sort of thing.

Imagine Consulting Company has become an Internet publishing consulting company, primarily targeting the Latin America market where they think there is a lot of opportunity. A lot of publishers there are going straight to the Web. Oh, let's see, what else are they doing? Some of the other stuff I mentioned, the enhanced classified ads. They have something called the Nando Bookstore where they sell all their reprints; a lot of their reporters have written books, and that's a good way to market those. Then they're also part of a national personal ads network.

I had interviewed Nandonet's CEO, Frank Daniels III, a few weeks ago for one of my columns, and basically what he said of his strategy is, "We want to get bloodied in as many ways as we can, because we know we'll heal." I think that given the state of today's on-line environment, where advertising or subscriber fees or no other one source can probably yet sustain your on-line operation, this is probably the best approach. Smaller newspapers are obviously not going to be able to do this; they'll just have to pick and choose a little bit.

Okay, I just want to talk about advertising a little bit. At this point, for on-line publishers, I think the best prospects for advertising continue to be those companies that already have Web sites of their own. As most of you probably know, on-line is not yet an easy ad, so it only

makes sense to go to those companies that already understand the promise of on-line publisher. Today that's primarily going to be some of the national advertisers, though I'm starting to see a few more local advertisers beginning to create their own Web sites.

I was talking to the ad manager at the *Los Angeles Times* on-line operation recently, and she told me that they're starting to see quite a few more local business come up with their own Web sites, which then gives them a lot more sales opportunities when they launch their Web site early next year. But you get some of the bad news that I was sharing from Los Angeles from the *Times*, and that's that they have had quite a fair amount of churn with their on-line advertising. They have been able to fill a lot of their spots, but it doesn't stick around for quite as long as it would in the print edition.

Now, what about newspaper's existing print advertisers that aren't yet on-line? Well, I think without a doubt they're also really prime prospects for bringing on-line. Newspapers already have this really nice, solid relationship with a big base of advertisers. So, what I generally recommend is that they also maybe set up a division within the newspaper company to help them help the advertiser's create their own on-line sites.

What I've found from talking to various people in the industry is that they seem to have a little bit less success in just sort of selling an on-line ad in the same way that you would sell space in a newspaper. It's a little bit easier if you can help give the advertiser what they want and what you have, which is an on-line site of their own. I mentioned NandoNet as this one company that is already done that.

Another good example of this is a small weekly in southern Maine; this is a newspaper called the *Southern Maine Coastal Beacon*, it's a small weekly. It's one of the few companies that I can actually point to in the newspaper business that is making money on-line. This paper set up an Internet publishing division several months ago over the summer, and its already helped quite a few local businesses set up their own Web sites. It set up a bank Web site, a hotel, restaurant and I think an athletic shoe store chain. The *Beacon* does have sort of a traditional on-line newspaper service, and then that's what you see on the screen there, but that's not really much of a revenue generator for them. Most of their money comes from building Web sites for other folks, for their existing advertisers.

The newspaper's publisher, Jeff Baker, tells me that the revenues from his Internet publishing business, which consists of just a couple of people, already almost matches that from the newspaper; and he thinks that by the end of the year that he'll be making more money off of his Internet publishing division than he will from the newspaper itself. So, especially for a small publisher, I think this is a real interesting approach.

M: Wouldn't those local newspapers quickly saturate the area? Wouldn't that business be fairly finite for returns? Wouldn't they have to change the model?

Steve Outing: Yeah, the question was, wouldn't local newspaper just sort of saturate the market? I don't have a good answer to that one. That's probably true, but certainly that business is pretty competitive in that there are a lot of garage shops out there that are building Web sites. The one advantage that the newspapers have is just having that pre-established relationship with advertisers, and being able to just walk in there and say, "Oh, here's this other opportunity, have you considered that?"

I just want to make one last advertising point based on my research and talking to people. I think the idea of having a print sales person also sell sort of the on-line ads for the on-line service just doesn't seem to fly. I don't have a lot of examples of where that's worked. Actually, it's also been the experience that *Editor and Publisher* has reached on the site that I'm involved with. I think an advertising rep really needs to be focused on the on-line product if

they're going to succeed, and if the print product always comes first then your on-line product is probably in trouble.

Let's see, I just wanted to talk a little bit about competition, and I really want to point out that on-line is a very different environment for newspapers to be operating in. It's very different from what they're used to. Not only are they competing against other print publishers doing similar things, but they're also competing against broadcasters — you know, CNN, the local TV station, National Public Radio, that sort of thing. You're starting to see more competition from the on-line services. America Online just recently launched its first Digital City Service in Washington, D.C., and that's a direct competitor to the *Washington Post Digital Ink* service. And they'll be opening up some more of that instead of localized services around the country.

Now, some of the wire services like Reuters are setting up its own service. And then you're starting to see some of the sort of on-line "only news" services pop up like Rupert Murdoch's News Corp., Internet MCI's News Center Service, and then Global Network Navigator with its Web Review.

And then, of course, there's a lot of competition in the news business from entrepreneurs, companies like Individual, Inc. that are creating sort of news filtering services, some other companies like Farcast, ClariNet — you'll hear from Brad Templeton on ClariNet a little later this afternoon — and InfoSeek. I wanted to show you Yahoo's news page because now you can go search the Web on Yahoo, and one of the links is Headlines and you can get your national headlines from Yahoo now.

So I think the threat to newspapers, if they choose to go it alone, is particularly acute from broadcasters that CNN site on the screen a couple minutes ago. I think it's a particularly well-done site, but you see the CNN site is also very much like the *USA Today* Web site, but CNN just does a little bit of a better job using video and audio clips. So I wonder if, in that example, *USA Today* and CNN really should be operating a joint Web site instead of basically competing head-to-head.

Obviously, as a news publisher on the Web you're competing for people's time and Listservs, newsgroups, live chat, sending e-mail, just surfing the Web — you're competing against all of that stuff for people's time. It's a pretty tough environment to work in.

That kind of leads into my final point, which is that as a publisher you don't have to — and indeed you really shouldn't be — doing this alone. To succeed on-line I think you probably need to enter into a number of alliances, and a lot of newspapers have done that already. Allying with a local TV station is obviously a wise move. They might provide things like the radar television maps or aerial traffic reports, that sort of thing. You might ally with a local radio station, where you could maybe do a live chat version of a popular talk show, something like that. I am seeing a lot of newspapers ally with other organizations.

In yesterday's *Boston Globe* they're promoting their new boston.com service, and what this says is, "The *Boston Globe* is proud to join hands on the Internet with a list of four TV stations, three radio stations, and a whole bunch of other content providers."

So that's just the idea that they're not doing it alone. Actually, it's the first one I've seen where a newspaper has allied with multiple TV stations. That's kind of interesting. More common is like the service in Iowa called FYIowa, and I think it's the *Cedar Rapids Gazette* that is allied with one of the local TV stations and with another publication called *Iowa Farmer* and somebody else I can't remember right now. So anyway, the idea is just don't do it by yourself.

Before closing I'll also just mention two of the most significant feature alliances for newspapers. The first you may have heard about; it got a fair amount of publicity — although right now there's not much to show for it — and that is News Century Network. That's an alliance of nine of the largest U.S. newspaper chains, including the biggies: *New York Times*,

Times Mirror, Knight-Ridder, Gannett. It's establishing an alliance of on-line newspaper services and sort of creating a way to tie together many local services and share content.

The idea with NCN is to create a value to the newspaper members by creating a national content for all of its members. For example, what NCN might do is set up, say, a national skiing service that all of those newspapers would be able to include as part of their content. And apparently they'll also be providing some sort of a basic Associated Press facility in HTML format that would be used by all of the NCN members.

At-Home, which I mentioned earlier, is the cable effort to bring a super-fast Internet access into the home. Now, At-Home is supposed to go commercial in 1996, and it's likely to offer Internet access accounts for about \$30 a month for unlimited hours. Part of that the plan currently is that you would get the cable modem — I think they currently are about \$500 — and you would get that as part of your monthly payments.

[Tape change]

Steve Outing: ... set-top box if you subscribe to cable today. Now, what the At-Home model does is form alliances with the local cable companies, and then At-Home will be developing the national content and the local cable companies will be responsible for local content. Now, I've been to a couple conferences recently where I heard some cable executives speak, and they're generally pretty adamant about, "Well you know, we don't want to get into the content business." So obviously there there's some good opportunities for newspaper publishers to partner with them.

M: Do you have NCN or At-Home on the Web?

Steve Outing: At-Home is on the Web and NCN is not yet. The last I heard they're still searching for their CEO, so that's a little nebulous right now, but they do have a lot of working committees. People at all the various newspapers are working on this, so there's some alliance possibilities with At-Home, but it also — I wish when I was talking about newspapers as ISPs earlier [I had mentioned that] things like At-Home really represented a pretty serious competitive threat to newspapers going into the ISP business as well.

Okay, so let me just summarize quickly. Just to quickly summarize what I've talked about, I think my advice that I generally give to newspaper publishers is to at least for now really try and mine multiple revenue sources. You can't rely solely on advertising.

Collect ISP revenues while you can, because that's potentially sort of a short-term opportunity. Persevere through hard times. You know, I think we're going to see some cutbacks in the next year, but I continue to remain pretty optimistic that publishers will be able to start making some money off of this, and some of them hopefully in 1996. Hopefully, we're starting to get out of the experimental stage.

Target advertisers who are already on-line; you aren't likely to get newcomers on-line unless you have the department set up to create Web sites for local businesses. Sort of the idea of don't necessarily just sell ads on-line, but also sell Web site construction services to advertisers.

Have a separate advertising staff to sell your on-line product if you can possibly do that. It's got to be somebody's top priority, and not the second string.

One of the more important points is just make appropriate strategic alliances. In this business, joining forces with your enemies generally can make a lot more sense than to try to fight it out with them.

Take part in important joint ventures that come along, like News Century Network and At-Home. And I'm sure there will be other things coming along that will be significant to the publishing business.

Remember that your print competition is not just other print publishers. The Web is king today, but what will it be in two years? Certainly I still think the Web will be around, of course, but I don't have a good idea what that's going to look like. So my point is just that publishers really have to stay on top of the technology. Anybody who is doing this sort of service should be experimenting with *Java* and doing all that stuff.

Okay, so I just wanted to leave you with a couple of URLs for some resources that I think you might be interested in if you're involved in this business or interested in it. One is the *Editor and Publisher* interactive Web site that I'm involved with. You will find a lot of interactive news there and you'll find a five-day a week column that I write called "Stop the Presses" and there is the URL. I'd love it if you would read that. That's available only on the Web, by the way, and not anywhere else. One of the things that I do for E&P is that I maintain something called the "On-line Newspaper Services Resource Directory," and there you'll find information of currently about 540 papers and what they're doing on-line. That includes contact information and description of the services, that sort of thing.

So, I think that's about it. So, if there are any questions that I can answer?

M: What is your personal opinion about viability of NCN?

Steve Outing: The question was, what's my personal opinion about of NCN? Well, it sounds like a wonderful idea in concept, but I think it's going to be very difficult to pull off. You've got nine companies involved, and at this point I don't know that there's sort of one real leader in that. I think the idea of all nine of them being able to cooperate is going to be a really tough nut to crack. I hope they can do it, but I don't know. Way in the back there.

M: [inaudible]

Steve Outing: Well, I think generally I don't believe that just re-purposing content is — that obviously can't be enough. I mean, certainly that's important. I've been kind of interested in talking to some on-line newspaper practitioners and in finding out what their most popular features are. I have been on-line for a while and so I've always expected that it would be the interactivity that is the big draw; but what I find from talking to a lot of people is that their most used feature is simply reading news on a computer screen. I have a hard time understanding why that's so compelling. I think that is really important, but I just think that you really have to have a balance, and the interactivity is just so important in creating a service like this. You have to create it so that it fits the medium.

M: How are newspapers differentiating themselves, aside from geographically, from sort of focusing on Raleigh or D.C.? What sort of examples of real creativity have you seen out there?

Steve Outing: Well, I mentioned the niche services. I'm seeing a lot of those, and a good example of that might be the *Cleveland Plain Dealer*. They've recently launched a site called rockhall.com and that's a partnership between the newspaper and the Rock-and-Roll Hall of Fame. There are a lot of services like that. Some of them will partner up, say with a local museum, and create — there's a site called The Yuckiest Site On The Internet which was launched a month or so ago, and that's a partnership between Newhouse Newspapers and I think the Liberties Science Museum in New Jersey. They've created a kid's site. I don't think

that's the advertiser-supported right now, but they might be able to support that sort of thing by grant money, development money, or through simply finding corporate sponsors. So yeah, I am seeing a lot of creativity in the business.

M: What do you think about personalization [inaudible]

Steve Outing: The question was about personalization, and what I think of how that's shaping up. The newspapers themselves have been a little bit slow to take that technology and implement it on their on-line services. It seems like more of the activity in that area has been going on by entrepreneurial companies like Individual. Microsoft Network apparently has an alliance with Individual, and Microsoft Network also has its own forty person news room. So that presents a pretty serious competitor to newspapers. What I think we'll all probably see is more papers starting to get involved with that. I think that's certainly one of the most compelling services that a newspaper can provide on-line. Back there.

M: How would you suggest collecting their fees, by doing it on-line [inaudible] transaction server?

Steve Outing: The question was about how newspapers are collecting their fees. As when I went through that list of different revenue sources, people are trying lots of different things. I did mention that the *San Jose Mercury News* was collecting a monthly fee, but that's actually the minority. Most of them are still offering everything for free and supporting it by advertising and other revenue sources, and I'm not seeing one particular revenue model that's dominant yet. Everybody wants to collect some fees from on-line transactions, but I can't point to very many people, at least on the Web, who are doing that. Now, on some of the proprietary on-line services, like some of the ones on Prodigy, their on-line commerce is a little bit more established and some publishers are making money that way.

M: [inaudible]

Steve Outing: Pardon?

M: [inaudible]

Steve Outing: Oh, we should have talked about Lexis-Nexis being fee-based. Back there.

M: [inaudible]

Steve Outing: The question was, is there a difference between business models between newspapers and magazines? Well, certainly that's true, but as I mentioned quite a few newspapers are developing these little niche services that will serve a national audience. For example, the *Boston Globe's* Web service that I just mentioned was just launched publicly. They had a skiing service there, so that's going to be of interest not just to Boston locally, of course, but the entire New England region. If one of the Denver papers, where I happen to live, put out a skiing service that would probably be a national service.

M: How would they adjust their business model to be responsive to the Denver newspaper, now that they're creating this? What new alliances would they have to build?

Steve Outing: Well, let's see if I can figure out how to answer your question. An example might be NandoNet, which I was talking about earlier. Now, they started out with a local model selling Internet services, selling ISP accounts locally, but they evolved their sort of on-line Web newspaper to be of national interest. Nando doesn't sound like a local product necessarily. They created something called the Sports Server which is really a competitor to ESPNET and those sort of services. Yeah?

M: [inaudible]

Steve Outing: Right. Yeah, that's an interesting point, too. I didn't really touch on the expatriate market. Quite a few newspapers, including some outside of the U.S. I could think of — there's a Web site in Glasgow, Scotland, and it's one of the tabloids; and they set up their Web site and if you go there you can go to a "Letters to the Editor" page, and the last time I visited all of the letters to the editor were from outside of the country. So that's a good potential market.

Let's see. How are we doing for time here? Three minutes left. So, are there any more questions or we can all take a break? Oh, one more.

M: All these things are current information directories and so forth. Is anybody mining their back files?

Steve Outing: Mining their files, their archives?

Yes, quite a few. The *San Jose Mercury News*, for example, has had its on-line archive on America Online since the beginning and they charge — I don't remember exactly, something like 15 cents a minute during off hours and 80 cents a minute during peak times. One of the comments that I heard from them which was interesting is that when they opened up their archives on America Online, they worried about, "Well what's going to happen to our revenues from the premium database services like Lexis-Nexis, the Data Times?" And they discovered it really didn't have any impact, it was just an additional revenue stream for them. I don't know if that will continue to hold long term, but initially it was a new market for them to market their archives.

Okay, well it looks like we're about out of time, so thank you very much.

PUBLISHING ON THE INTERNET THE CULTURAL, LEGAL, AND SOCIAL ASPECTS OF CYBERSPACE

SPEAKER

Vic Sussman

Senior Editor/Cyberspace, *U.S. News & World Report*

Vic Sussman: Thank you. I did not name this session, by the way. Neither did Walter, but when people from Mecklermedia asked me, they said, “What do you do?” And I said, “Well, I write about the legal, social and cultural aspects of cyberspace,” and that’s what they called it. I mean, if I had said, “I don’t know,” that’s probably what they would have called it too. My title, actually, at the magazine is Senior Editor/Cyberspace. That was given to me by one of our PR people, and I decided that they would have to pry it from my cold, dead fingers to make me give it up because it makes me feel like a character out of a Raymond Chandler novel.

You know, I cover cyberspace. Although I know a lot of people hate the term “cyberspace,” it beats “information highway.” I’d like to spend about the next thirty minutes doing an extended rant, and at the end of it I will say, “end of rant.” I should tell you that my comments do not represent the opinions of my employer, *U.S. News and World Report*, and they would probably tell you “and not anyone else in their right mind, either.” But as somebody who covers this and basically created the cyberspace beat at *U.S. News* by rattling cages for several years and saying, “You know, something is happening here and you don’t know what it is,” I’d like to talk a little bit about the way I see things, and particularly the way I see things in the media — and try to do this without picking on my colleagues too much. But many of them deserve it.

So I usually call my talk “Fear And Loathing In Cyberspace,” because actually I think that’s the phase we’re in now. We are in the fear and loathing stage, and that seems to happen if you read your [inaudible]; it’s essentially what happens whenever there’s a new technology that comes along, especially a new communications technology — society tends to go through periods where there’s great fear and loathing.

You’ve probably heard the story that when the automobile was first developed there were municipal laws that mandated that someone had to ride in front of the approaching automobile on horseback, ringing a bell and warning people that the car was coming. There were also other people who made predictions that no automobile would exceed 25 miles an hour because humans wouldn’t be able to breathe at that speed.

I remember talking with Dave Farber at the University of Pennsylvania, who was involved in modem development, and Dave said there was a time when they hit three hundred what they called “baud” at that time, and they felt that they had really pushed the envelope as far as it would go.

So this is really a historical period, but I think that the period we’re in now with regard to the network world — we have an advantage over people in the past, and I think that is because of the development in technology in the last fifty years. I think we have much more perspective than the people who feared the automobile. In fact, I have a button that I picked up in a shop — and I can’t tell you exactly what it says or they’ll turn this place into a supermarket — but essentially it says, “This is the ‘90s. Where’s my air car and robot?” I left one word out — it’s a little more explicit as a button — but if you remember, the ‘90s were supposed to have skyways and airways and you know, you can’t even get across town, especially in this town, because they keep tearing up the roads.

But I think with this technology, in fact, we should be much more settled about this and we should be able to look with much more perspective and see what’s coming. Now no one

knows what's coming and I like to say to people, "If three or let's say four years ago you had said you envisioned a company producing browsers," what would the reaction of people have been?

Or if you had said in 1980, "The concept of the WorldWide Web is the embodiment of human knowledge," as Tim Berners-Lee grandly and probably accurately calls it.

Or even if a couple a years ago you said, "I have an idea for having audio and real-time [video] come over your computer." I mean, all of these things have come fairly rapidly, and I like to tell people that covering cyberspace is like being a reporter who covers the Justice Department, and every morning I have to go to the Justice Department to a 10:00 briefing — and every morning when I get there they've moved the building and they haven't told me where they've put it. Covering cyberspace is a lot like that.

My plan, ultimately, is to have cosmetic surgery — I'm going to have my appendix taken out and my modem put in so I can be like [inaudible], I can jack in from anywhere. The only problem is I don't know where they would put the mouse.

So, to tell you how I got started in this... I am not a techie, I don't come from a technical background. Basically I'm a kid whose entire life was changed when my dad and I built a crystal radio. And I can remember my father and I sitting at the kitchen table and winding the wire around an oatmeal box, a Quaker Oaks box with the germanium diode and the cat's whiskers and one earphone, and I remember vividly being about 8 or 9 years old and I put the earphone on and my father said, "Now watch what happens," and he touched the bare wire, or I think I did as a child.

He had scraped some paint off the radiator — I'm dating myself, but nobody else would — and I remember touching the bare wire to the radiator and hearing static crackle in my ear and then music which was coming from a foreign country. We were living in New York and the music was coming from New Jersey. And I remember just being absolutely knocked out. It was like magic.

Walter was teasing me, because he knows my hobby is actually magic — which has figured into this too. Arthur Clarke has said, "When a technology advances sufficiently it appears to be magic," and for me as a little kid this was magic. And I knew at that time that I wanted to do something that had to do with this technology.

Now, what's interesting is that last year in Boston I met Len Kleinrock, who is one of the pioneers of ARPANET and Len and I were talking and I asked, "How did you become a scientist?" He built a crystal radio as a little kid on the east side of New York, and I said, "Isn't it interesting that my experience with a crystal radio pushed me into broadcasting, yours pushed you into actually the science of the physics behind broadcasting and the physics behind computers?"

But at that age I knew that's what I wanted to do, and so when computers came along I didn't get involved. You would think that I would probably want to jump right in, but at that point I was going though my [inaudible] and I decided that I wanted to live in the woods and grow my own vegetables, and computers at that point were just — I mean the idea of computers just disgusted me. Everything that was wrong with society was being embodied in computers.

Now, I was a freelance writer at the time, living in northern Vermont. I owned a 23-acre farm, and I belonged to a writers' group and we used to have monthly meetings of the few writers that lived in this part of the world. I remember the monthly meeting that I went to in 1982 was at the beginning of what turned out to be a blizzard, and I went to a friend's home and I remember driving through the increasing snowfall, walking into his 100 year-old Vermont farmhouse — and he and his wife had just purchased an IBM personal computer for \$5,000.

It was, you're laughing... It was 128K or something like that, and I think my watch actually has more than that. But I remember walking in, the smell of wood smoke permeating his home, walking into this room and here is this computer which I had already made up my mind I was going to hate — until I saw him demonstrate what he called "word processing." And I remember turning to a friend of mine and rather grandiosely saying, "I have seen the future, and it's digital." And I knew right then that I had to have a computer, because it meant no more note cards. Well, at least I thought that at the time.

There's something to be said for analog, as I found out later. But I knew at that point, when I saw that cursor go across and I thought, "you know, I've been buying White-Out by the spray can and this is amazing to me."

So I remember going into St. Johnsbury, Vermont, and they had one computer store and they sold Osbornes. Remember the Osborne? Four inch screen — actually three and three quarter inches, measured diagonally — it was amber, weighed 25 pounds and looked like a Singer Sewing Machine. It was my first laptop and I remember going in the store and saying to the salesman, "Why should I buy one now when they're obviously going to get better and cheaper?" And he said, "Because if you wait five years you're going to go five more years without a computer." So for \$2,000 I walked out with an Osborne that had 64K and I thought I owned the world at that point. I literally lugged that machine everywhere. It changed my life as a writer, and it was the end of my [inaudible] phase.

So I feel very comfortable talking about what's being called the "new [inaudible] Kirkpatrick Sale" you've probably heard about. Ah, Kirkpatrick Sale smashes computers on stages to demonstrate his loathing for technology and then goes back to his air-conditioned apartment. I imagine he probably takes computer-controlled airplanes to get from place to place, unless he's walking.

I've already been through this phase; I've spent 16 years growing my own food and I delivered my daughter at home, so don't tell me about do-it-yourself, I've been there. And I am absolutely in love with this technology. Yet the first demonstration that I had of going on-line, I had the initial reaction which was, "I'm never going to do this." Why? Because I interviewed, for a column I was writing for the *Washington Post*, a woman who had become psychologically — I couldn't say physically, but psychologically — addicted to live chat lines. Now, fortunately her husband was a doctor so they could afford the \$300 phone bills that she was running up every month. But it really soured me. I liked her and we're still friends, she's now a sysop for CompuServe, so that's how you turn your addiction into something positive. And she actually became a travel agent because she became so experienced with computers that she went on from there.

But it really soured me, and the reason was I thought, "I don't like to hang around bars, why do I want to go out in what we call cyberspace and talk to strangers?" It seemed stupid to me. So the turning point came when a very close friend of mine, who happens to be a professional magician — so we're back to that again — is leaving Washington, moving to New York and says, "Let's keep in touch though e-mail," and I said, "Jamie, I don't do e-mail; I do e-mail at the office and it's very impersonal, I don't really want to do it."

Now, my friend Jamie Swiss — who's one of the country's best close-up magicians — looks me in the eye and he says to me, "You know, there's a whole universe out there and you don't know what it is." Well, I thought, that's a personal challenge and I can't run away from that, so I got a CompuServe account.

It took me roughly twelve hours and it was like St. Paul on the way to Damascus being struck by lightning. Did you ever notice that people who discover the on-line world are like reformed drunks? You know, they have to convince everybody. Or it's like when I first became a vegetarian 26 years ago; you stop people in cafeteria lines and say, "Do you know what that

is?” You know, it’s a horrible phase that you go through and this is what happened to me. I came into *U.S. News* and I said, “You know, this is amazing.”

Well I apparently was the only one who thought so, but from there I went on and got accounts on America Online and Prodigy and The WELL and just all over the place, and that’s when the jokes started about the fact that my wife started referring to herself as an Internet widow and this sort of thing; going through the whole thing. But at that point I really became convinced that my friend Jamie was right, there was a universe and I didn’t know what it was and most people didn’t know what it was, but it was not going to go away.

My favorite comment is when people say, “Well you know, this is like CB radio, it’s going to go away.” Well then, if it’s CB radio I could probably use my old handle, the Big Soybean. That’s what I used to use. Mr. Natural was taken — I tried to get that on America Online.

So that’s how I became involved, and I would say — as corny as this sounds, this many years later this really is corny — but every time I log on and there’s mail from wherever I get the same kick that I got when I first logged on. It’s still amazes me and I hope it will always continue to amaze me. It is magic, it is absolutely staggering to me.

[Robert Sideman] — I’ll embarrass [Robert Sideman], the editor, publisher, and owner of *Sideman’s Online Insider*, he’s a friend of mine and he’s in the audience — and we were talking about this before, and I now divide people into categories. Robert and I got to know each other through e-mail and then finally met face to face. That’s one category of friendship. I have other people I met face to face but we never got to see each other again, so we became friends through e-mail. And then there are people I’m probably never going to meet who are in different parts of the world that I would consider actual friends because we share large amounts of information.

So I’ll talk about that in a minute too, the idea that this fear and loathing is going to isolate us — and of course most of us, I think, have found that it’s exactly the opposite. Now, having said that I’m absolutely in love with this technology and that the feeling doesn’t really go away, let me talk about my anger about some of this. And, Walter, I forgot to set my timer, so give me a heads-up, because once I push my own hot buttons, you’ve got to watch out.

I think the media has mishandled this story very, very badly for the most part. Let me give you some examples. This is my favorite example; this is probably three months ago, maybe four months ago at the height of the hysteria over cyberporn. You probably all saw my competitors’ cover story, “Cyberporn.” I like to introduce myself as someone who works for the weekly news magazine that does not have to issue apologies for the cover stories that we write. I’ll come back to that.

If Philip Elmer Dewitt is here — hi, Phil. About four months ago or whenever it was, Ted Koppel did a show about “what’s not being called cyberporn,” and his show was basically what can we do about it. You know, we know it exists — what can we do about it? His guests were Mike Godwin from the Electronic Frontier Foundation and Ralph Reed from the Christian Coalition.

Now, normally you’re writing your own jokes out there, and normally I don’t like to watch shows like this because they’re not good for my blood pressure, but it’s Ted Koppel, the dean of American television journalism — which actually is an oxymoron — and so I’m watching this show and Ralph Reed tells a story, and this is the way the story goes, this is pretty much verbatim. He said — “we” meaning his organization — “We know of a woman who wanted her child to learn the Internet” — now right there my syntax meter, my spider sense is tingling — “who wanted her child to learn Internet so she went out and she bought the software, and she came home” — now these are Ralph’s words — “she came home, she

popped the software into the computer and then she left the room for five minutes and when she came back her eight-year-old child had downloaded scenes of bestiality.”

Well, my initial reaction was that this is a child with a very bright future in computers. I also wanted to know where she bought the software, because with the SLIP and PPP and a 56K line... And what amazed me is that Koppel never stopped him and said, “Ralph, are you out of your mind?” I mean, that’s what I would say if I was sitting on the show: “Ralph, have you had your medication adjusted? What kind of story is this?”

And of course Godwin, who could have eaten him alive, really wasn’t given a chance to respond to this. So when I came down off the ceiling I continued to watch the show, and this was my favorite part: Ted Koppel says — see, Ralph Reed makes the point that there have to be tight government controls over content because the American public cannot be trusted to police itself or it’s own family — and Koppel says “Well, you know, I have to agree with that,” and Godwin says, “Now wait a minute, we’re intelligent people, people should be able to run their own families the way they want to,” and Koppel says, “No, no, I’m the best example you could have. I don’t know anything about computers. My kids know more about computers than I do, I am a big dummy about computers,” at which point I have to be restrained because I’m almost frothing at the mouth.

This is what occurs to me and this is what I want you to imagine, and this is where we are with the media and this new technology. I want you to imagine Ted Koppel or David Brinkley — who is another one, by the way, who has said publicly that he does not like computers and that he uses them only to process words — I want you to imagine someone like Ted Koppel — now I’ve killed my chances for being on the show, you realize that — I want you to imagine him saying some night as the program *Nightline* opens that he looks directly into the camera, into the hearts and souls of the American people and he says, “Ladies and gentleman, I don’t know anything about the health care problems in this country, I haven’t got a clue about it, my kids know more about health care than I do, in fact I think it’s really funny that I’m so stupid about this. And tonight’s show is about health care and I’m going to be asking the questions.”

So it has become fashionable; I think that’s probably what it is. We all hated the guys in high school who were on the AV squad, right? The guys with the retractable key chains. I played chess with them, so I never had that problem. I thought they were cool. What do you think Bill Gates is? I mean, that’s the revenge of the nerds, right? But it has somehow become fashionable now to be stupid about technology. Maybe we need a sociologist in the room so I can lie down for fifty minutes and talk about this, but it seems to me that this goes back to our mythical pioneer roots, the rugged American, the “we don’t need this effete technology, all I need is my ax and I can go out into the wilderness.” American men still believe that, they still believe that if they were dropped by helicopter into the Mojave Desert they could get out, maybe with an American Express card but not with a Boy Scout knife.

We do have a kind of schizophrenic attitude in America about loving technology and hating it at the same time, and this may be part of that. This is probably an article I should write at some point, why it is so fashionable for people to say, “I don’t know anything about computers.” I’m told it’s a generational thing. I’m told by younger people who have grown up with computers, like my kids — by the way, you know the reason I decided to get a Macintosh was I was tired of talking CP/M to my son, it didn’t seem like a good way to have a father-son relationship, saying “control D” and then, you know — but it seems to me that there is a generational thing and I hear this all the time, that if you’re over 40 you don’t know how to use a computer and you’ll never learn. Well, I’m over 40 and that’s just ridiculous to me.

Now the other time that this same thing happened was even more shocking than Ted Koppel, and I am picking on Ted Koppel because he should know better. When I was at a

House science subcommittee hearing, also on cyberporn, and I heard congressman after congressman — and they were congressmen, not congresswomen, and by the way, the Chair of that subcommittee is Connie Morella, who happens to be my congresswoman, Connie did not say this — but the men, all of them said “I’m over 40 and I don’t know this stuff.

And one congressman said, “I went out and bought a book called *Computers for Dummies*” and a congressman at the other end said, “No, no you should have bought the other book, it’s called *Computers for Congressman*.” So it’s a great line, you know, until you stop and think that the next thing the congressman said is, “I have to vote on a bill about this.”

So, in other words, now I’m thinking, “Gee I wonder if he knows nothing about agriculture, if he knows nothing about defense. This must be democracy in action” is all I can think of. But to sit up there and say “I don’t know anything about this and I can’t learn to do it.” He can navigate a 3,000 pound automobile through traffic but he’s afraid if he pushed the wrong key it will blow up in his face? I mean, this is why children are so wonderful, they don’t worry about breaking things.

You know, that’s why kids can sit down at a keyboard and get peanut butter between the keys and everything — they didn’t buy it, they don’t have to pay for it, it’s not going to blow up, they don’t care and they have a wonderful time. So maybe we have to be more childlike about this. But this is what’s happening, is that we have people [like this] on Capitol Hill.

Now I’ll talk about the Exon Amendment; that was a wonderful period in our history which is of course still affecting us. Senator Exon from Nebraska, who is not running for re-election, whose... I always think it’s sort of like if Senator Exon took a plane directly from Lincoln, Nebraska to Times Square and landed by helicopter right in Times Square, got out of the helicopter, walked directly into a porno shop, was properly shocked at what he saw, got back on the helicopter, flew back to Nebraska and said, “I’ve been to New York and it is a cesspool.” He didn’t go to the museums, he didn’t go to the libraries, he just went one place and was properly shocked.

Essentially that is what’s happened, because I called the Senator’s staff and I said, “Would you please tell me what the Senator’s experience is with the on-line world?” The answer was quite honest: “None, except that someone sat him down and said isn’t this awful.” So I said, “Uh, that means I can go into print in the magazine and say, Senator Exon’s only experience on the Internet is looking for pornography.” Which is essentially true.

Now we have also heard that Senator Exon has the book he calls the “blue binder,” which is filled, apparently, with photographs of child pornography and photographs of bestiality. I find this, as a reporter, I find this probably one of the biggest stories of the year, because as you probably know, mere possession of child pornography is a federal offense. Why have they not arrested this man? Not only does he possess this material, he is walking around Capital Hill showing it to other people. So what we have is a kind of hysteria.

The other hysteria has to do with, of course, terrorism. I went to a Senate hearing this time, the Senate subcommittee on terrorism, and Senator Diane Feinstein went off because she was concerned that there was bomb-making information on the Internet. One of the panelists, one of the witnesses pointed out, held up a book — I’m trying to remember the name of it, something like the, well not the *Bomb Maker’s Manual*, but something like that.

M: *Poor Man’s James Bond*?

Vic Sussman: No it was not the *Poor Man’s James Bond*.

M: [inaudible]

Vic Sussman: No it was not the *Anarchist Cookbook*. This is a very well-read audience. It was something like the *Dynamiter's Handbook*, and he pointed out that it was published by the United States Forest Service and it told how to make bombs using fertilizer, and this was after Oklahoma City. And Senator Feinstein said she was shocked that this information was being disseminated by the government and was on the Internet, and she wanted to have a law against it.

Then Jerry Berman from the Center for Democracy and Technology said, "You know, we have a First Amendment that says you don't really regulate content," and she said, "Well I think that's wrong."

You know, this is what happened. And then Arlen Specter held up the *Big Book of Mischief*, remember that one? Remember that one? *Big Book of Mischief*, a mayhem manual, had been pulled off the Internet.

Of course, immediately afterwards I went and got the URL so I could download that and take a look at it, and Jack Rickard, the editor of *Boardwatch*, and I shared some mail about this. The consensus is that the material that's in a lot of these books really should be disseminated, because we will then be able to identify the potential terrorists. They will be the guys who have fingers missing, because most of the material in this is pretty unprofessional.

I have friends in law enforcement and I have discussed this with them for stories I've written, and they have told me to a man that the really bad guys do not use the Internet to get information about how to kill people, they have basically learned it in prison and if they need to get a gun they do not get an AOL account.

But again, what you have is new technology, so it's very frightening to think of eight year-old junior sitting down and downloading bomb-making information, and he doesn't know what to do this afternoon, whether he should look at his bestiality collection or whether he should blow up the neighborhood. It's a tough choice for a little kid.

There was a case about two years ago, the Michael Alansky case in Hartford, Connecticut. Michael Alansky was 18 years old, and he was arrested for running a bulletin board system and disseminating bomb-making information, among other things, to minors. He was arrested, he was put in jail, and when he came up before the Judge for bond — this was after the World Trade Center bombing, bad timing on Michael's part — and Michael had not blown anything up.

I do not know Michael, by the way, even though I'm calling him by a first name. He had simply had a bulletin board, and he did not write the information, he was disseminating. It had been written by a 16 year-old who had culled it, he later said in an affidavit, from college chemistry books. So he said, "I don't even know if this stuff works, really." And so these are bad boys putting stuff up on BBSs and downloading it. Michael comes before the Judge, the Judge levies a bond of \$500,000 and says, "I consider you just as dangerous as the people who bombed the World Trade Center." The kid goes to jail for one year, his parents cannot get him out.

Now, I wrote about this, and Mike talked about this — the EFF was trying to represent the Alansky case — the kid basically languished in jail. I talked to Jack Rickard about it and Jack said, "Well, one of the problems is Michael Alansky is no angel, he does have a juvenile record. He has been involved in explosives apparently, pipe bombs, never hurt anybody, no history of violence, never really blew up anything."

Well, I have to admit as a Senior Editor at a major news magazine that I have blown things up in my time too. How many guys in this room at the age of 15 or so had a fascination with, not bombs, but had a fascination with things that go boom? Okay. How many women in

the room at the age of 15 had a fascination with things that blow up? It's a guy thing. In Michael Alansky's case a year in prison, in jail, without a trial...

During that time he was physically assaulted and he also witnessed another prisoner commit suicide. His parents could not get him out. At the end of a year he copped a plea, essentially confessing to a probation violation for an earlier juvenile offense, and he got out. He lost all of his computer equipment and he lost a year of his life. And what did he do? He provided information that is available a couple of miles from his house. You mentioned the *Anarchist Cookbook*. That book is for sale in Hartford, Connecticut, at a book store not far from Alansky's house. So what you have — and I'm not making a plea for bomb makers of the world — all I'm saying is that if you're going to have a First Amendment and you're going to disseminate this information in a bookstore, why is it wrong when you're disseminating on the Internet?

Well, the theory is, as I understand it from senators and congressmen, is that it's easier for people to get out. I'll wait while you laugh; because those of you who have been using the Net for a while, if you think it's easier to FTP than it is to go to the bookstore or go out to your newsstand and buy a copy of *Solider of Fortune* and just go through the ads in the back or get a copy of *Popular Mechanics* and get the ads that say pyrotechnics in the back, and get the catalogs...

I mean, this is really nutty to me. It is absolutely nutty to me. And what's really nutty is that at 18, at 16, at 15 any kid can walk into a bookstore and buy a copy of *Solider of Fortune*. There's no law against buying *Guns and Ammo* or buying any magazine that purveys implements of violence. We don't have a law against that because we have a First Amendment.

The example I always use is Howard Stern, another bomb maker; his show is, anyway. Howard Stern can write anything he wants in his book and he is covered by the First Amendment, but if he reads it on the radio he gets fined, and that is the strange attitude that we have in this country about the Bill of Rights, certainly about the First Amendment. That we have this strange attitude about content regulation. So this is really where we are.

And now we're seeing the other scary thing besides the bomb makers and the pornographers are the hackers and the crackers — and of course most people in the media don't know the difference historically between a hacker and a cracker, so they're all hackers in their view.

I wrote an article about a month ago about how computers are portrayed in the movies. Last summer we had the movie *The Net*, we had *Virtuosity*, we had *Johnny Mnemonic*, which disappeared like a stone. I never got to see it, it disappeared so fast. It was a great idea, it was from the Gibson novel, what a great idea. The guy uses his head as a store — he couldn't afford a zip drive, you know, so he has to use his head — and somebody is going to cut his head off, they've never heard of encryption. I don't understand it but I wanted to see the movie.

And then the other movie was *Hackers*, which glorified it, which I said in my article. It was about young people who made the world safe for people who wear their baseball caps on backwards. But in every one of these movies the computer is essentially evil.

You can really divide the way we approach computers in popular [culture] into about three categories. We have movies in which the computer is simply evil and we have movies in which the computer is a good computer but becomes evil. I mean, one example would be probably *HAL 9000*, which is a classic example; although really if you read the short story it was taken from [you'd see] HAL had a conflict, he wasn't suppose to tell them what the mission was. But he also wasn't suppose to hurt them; it was Asimov's law and he just got so conflicted that he went nuts. So you give HAL a little benefit of the doubt.

But then you have a movie like the *Demon Seed* in which Protius 4 — I know how you guys spend your time, my God — Protius 4 figures out that they're going to pull his plug because he's too smart, so he impregnates Julie Christie. I'm using "impregnate" so I don't have to say "rape," but that's what it was in the film. Not explicit, but still awful. Yes, they have a baby, and I don't want to spoil the ending for you, but you can't really run out and see the *Demon Seed*.

In all these films the computer... Now there are also films in which the computer is neutral but the people are bad and they use the computer for evil purposes. And then there are movies like *Sneakers*, in which the computer is kind of neutral and the guys are both good and bad at the same time.

But nobody shows movies in which the computer plays a roll that it plays in my life, and I suspect in most of your lives. I talked to Roger Ebert about this and Roger e-mailed me and he said, "Well, you know, it really wouldn't make an interesting movie to have a movie about an airlines reservation clerk whose life is enhanced by a computer, because the nature of dramatic conflict is such that you have to have a bad guy and it's easier to show the computer as an object of evil than it is to show it as something that is positive."

The problem is that all of these movies... And Hollywood is finding out; none of these movies were terribly successful. And by the way I saw all of them except for *Johnny Mnemonic*, and even the people who loved *Johnny Mnemonic*, even Mike Godwin, whose name on *The WELL* is "Mnemonic," didn't like *Johnny Mnemonic*. But I still want to see it.

But in all of these movies, they didn't do well financially at the box office, and the reason is because no matter what you do in Hollywood you still wind up with people typing. And people typing is not really interesting, so you have to glitz it up and the filmmakers do wonderful things. I think in *Hackers* you see that they are looking at the screen and typing and on their faces are the letters reversed from the glow of the computer screen, isn't that correct? And in *Sneakers*, every time they hit a key the letters tick on the screen, they make a little ticking noise, so they have to do this to kind of jazz it up.

Now, the next movie I'm waiting for is the *Kevin Mitnick Story*, and actually John Markoff, as you know, has written a book about the capture of Kevin Mitnick, arch fiend that he is. Anybody know where Kevin Mitnick is? He could be here by the way, if he's out, but how are they going to make a movie about Kevin Mitnick, the Uber Hacker?

You know, as one cop told me, the "Hannibal Lecter of hacking?" How are they going to make a movie about this overgrown kid who steals 20,000 credit accounts from NETCOM, then put it on a publicly accessible machine? That was written about in *2600 Magazine*, but that's another story; I don't want to embarrass Mr. [Garison], if he's here.

So Mitnick steals these things but he doesn't make any money. How are we going to make a movie? You have to make Kevin Mitnick really bad, you have to make him like Hannibal Lecter, but that's not really true. No, so you have to make Kevin Mitnick heroic — but we really can't do that, they can't make the movie. I just don't think Markoff can sell this, even though Miramax has an option on this script by the way, or on the story. I don't see how they can make that movie.

Because Hollywood — and I'm using Hollywood generically — they have to cast computers in a bad light. The only thing that I would say, and people always say this to me, is *Star Trek*, but my article was about movies. In *Star Trek*, certainly the computers are constructive in that sense. So, I think this is where we are, in this fear and loathing sense.

And now we're moving into another phase and that is the "Cliff Stoll" phase. Cliff wrote a book called *Silicon Snake Oil* for which he is now touring the country, making speeches, telling us that he has misspent his youth, essentially, and that computers are a very bad thing because

as he says in the book, "if you are on-line it's not the real world, and you should be out growing tomatoes."

Well, I don't know about you but I had tomato plants this year and I was on-line. I guess I'm just a polymorph. A friend of mine, [Glee Willis], e-mailed me some time back and Glee is an engineering librarian at the University of Reno and Glee said, "You know, I wonder if Cliff Stoll would have felt that computers were a terrible waste of time back when he caught the hackers." It's a good question.

Somebody else in a magazine, in a letter to the editor, said, "I think maybe he's going through a mid-life crisis, that he's now looking back on all the time he's spent in the basement with a computer and he's saying, 'gee, there's a whole world out there.'"

But in fact, I don't think computers isolate us at all. I think people who isolate themselves are going to be isolated whether they use a computer or not. But this also buys into this New Luddites attitude, that somehow computers are spoiling our lives. As I say, as somebody who went through the, you know... It's actually not fair to call them Luddites; the actual Luddites were mostly men who believed that their jobs were threatened by the new technology, and they were smashing equipment to save their jobs. The New Luddites are hardly blue collar; [they're] a lot of PhDs telling us that this is going to ruin our lives.

So let me tell you two stories and then if there are questions about life, the universe and everything I'll answer those. I'll tell you two stories about computers.

I have a four-year-old son who tends to get high fevers. I think he's growing out of it now, but when he was about 2 or about 18 months old he would get very high fevers that would spike very fast; it would go up to like 105 — I mean, I'd be dead, you know. But this [one time], at 102, he's running around playing ball. And sometimes, when children are subject to high fevers they get what's called a "[febrile] seizure," and that's simply where the brain is overwhelmed by the rapid rise in temperature and the child has a convulsion. This is what happened to my son.

I was at work at the time. We had a paper hanger in [the house working], and I get a phone call from the paper hanger saying "your son has had a convulsion, your wife is on the way to the hospital." I mean, that's the worst possible thing you could hear in the world.

Off to the hospital I go, the emergency room. Well, long story made short, [febrile] seizures do not harm children. Our pediatrician told us that. He did say there was a theory some years ago that there might be a link between them and the development of epilepsy, but for the most part there's no real danger to kids. But it is a really scary thing to see, and you have to guard your child so that when you see the temperature going up, you have to give them Advil or something, so on and so forth.

I really wasn't satisfied, it wasn't enough information for me. So I went on-line — and I'm the guy who said I don't talk to strangers — but I went on-line and I went into the MedLine SIG, on CompuServe. Now, I'm not pushing CompuServe just because *U.S. News* is on CompuServe; there are these groups on every on-line service. I chose MedLine. MedLine is populated by mostly medical professionals. And I posted a message and I basically told them what I just told you, my little boy suffered a [febrile] seizure, I'd like to know more about this.

Next morning I logged on, and here's a message from a woman who identifies herself as a pediatrician and a mother of four children, and she said she spent a lot of her time reassuring parents about febrile seizures, there's really nothing to worry about, the worse thing that can happen is when you put the child in the bathtub with cool water, trying to lower the temperature, you want to watch the kid doesn't hit his head; and the other worse thing that can happen is that the parents freak out and there's permanent damage to their psyche because of this.

That evening I logged back on and here was another message, this one from a man who identified himself as a pediatric neurologist, who gave me the history of the original studies that pointed a link between [febrile] seizures and epilepsy. He explained to me that the original studies were flawed and said you have really nothing to worry about.

I printed this information out and I gave it to my wife, and this is what I have done ever since. When I have a question, I go on-line. I want to hear what other people have to say. Now, people have said to me, "Well, how do you know he was really a pediatric neurologist? He could have been just posing [as one]. How do you know she really was a doctor?" Well, you know, I guess the simple answer is that I'm not that stupid, and the information that they gave me squared with the information I had gotten from other professionals. If they had told me to sacrifice a goat or something, I might have gone on The WELL at that point and checked it out there.

So I find myself in the position now where I no longer buy computer equipment, I would no longer by audio equipment, high fidelity equipment, I would no longer buy video equipment. I'm not sure I would really buy anything anymore of a substantial nature without going into the network world and saying, "Hey folks, what do you think?"

It's a very small town. I did this with a hard drive recently and I had trouble. It was an internal and I had a little trouble installing it, so I went in and said, "I'm having a little trouble with this." I get e-mail from somebody — I'll give them a plug, from APS — and it says, "I'm one of the help people, I saw your post." He's lurking, you know. He said, "I saw your post, here's my beeper number, if you have trouble call me at home over the weekend." They've got all my business now. I'm not going anywhere but APS at this point, because they have a customer relationship with me.

So this is a whole new world, a whole new world. The last story is about isolation, or the lack of isolation. And it has to do with a visit I made to Boston about a year ago.

[Tape change]

Vic Sussman: [I was] in a condominium, staring at the Atlantic Ocean, totally zoned out, but I logged on one morning to get my e-mail and I had a letter and the letter said, "You don't know me..." I love letters that start that way. I think it's from Kantor and Siegel when I get mail like that, you know: "You don't know me but, you can get your green card."

This letter said, "You don't know me but we talked a year ago on CompuServe, and you might wonder where I am right now and I'd like to tell you." And then he typed in his latitude and longitude — of course I instantly didn't know where he was — and then underneath that it said, "I am steaming through the Arctic Ocean on an icebreaker, headed for the North Pole." And of course I immediately wrote back and we started a correspondence.

Now, our correspondence was a little hampered by the fact that he was using a laptop on the icebreaker, bouncing the signal off the Lincoln 9 experimental satellite, which I believe is MIT's, and that signal was then sent to the University of Miami, which then put it onto the Internet which then eventually got to me. And so we continued to correspond and the guy happens to be a really wonderful writer, so I was getting these wonderful, wonderful travelogue letters from somebody on an icebreaker steaming toward the North Pole.

Some time in mid-August I got mail... By the way his name is Mike Powers, and he's the commander of the U.S. Coast Guard icebreaker *Polar Sea*, which is the largest non-nuclear icebreaker in the world. I must tell you that before I met Mike, I didn't know a lot about icebreakers. I [now] know a lot about icebreakers. Anything you want to know about icebreakers, I'll tell you. And so we continued to write and then some time in mid-August I got mail and it said, "Greetings, Vic, from the North Pole."

Now, I felt like I was 12 years old. I mean, I was 8 years old with the crystal radio again, it was Santa Claus writing me, it was unbelievable. I am sitting at my computer, staring at the Atlantic Ocean, and I am getting mail from someone at the North Pole.

I immediately wrote back and I said, "Mike, I've [never] heard of anyone sending e-mail from the North Pole. Would you check and see? You may be the first. And indeed the *Polar Sea* was the first to do that. They were also the first United States surface vessel ever to reach the North Pole.

Then I get mail from Mike and he says, "We're now steaming down through the North Atlantic, we're going to go down, we're going to go through the Panama Canal, and we will be the first U.S. surface vessel to circumnavigate North America and we're going back to our home port in Seattle. Oh, by the way, we broke a propeller blade at the North Pole, we have to put in for repairs at the Coast Guard support center in Boston, and we will be there."

Now, at this point, if your hands could shake while you're holding your laptop, my hands would have been shaking, because he tells me the date he's going to be in Boston is September 10th — and I am going to be in Boston on September 10, because I'm attending the 25th Anniversary of ARPANET. So I e-mailed back and said, "I'm going to be here." On September 11th, I walked up the gangplank of the U.S. Coast Guard icebreaker *Polar Sea* and shook hands with Mike Powers, and took Mike and his wife out to lunch. They are now back in Seattle.

This has turned into a constant friendship, by the way. Two or three months later, Mike steamed down to the South Pole and we continued to correspond. I toured the ship, I have the pictures to prove it. I would just tell you, given my personality and my background, that I don't meet a lot of Coast Guard commanders, of icebreakers or otherwise. And, at the risk of sounding a little flag-waving, I would also tell you that until this friendship occurred — and it could not have occurred any other way except the way it did — I had no idea how much the military gives to the people in this country. And it has changed me in many ways. My political attitudes in some sense [have changed], and certainly my attitudes towards people in the military have changed drastically from the way they were say, in the '60s.

So when I read Cliff Stoll and Kirkpatrick Sale telling me what a terrible technology this is, and how it's going to isolate me and how it will destroy public spaces and we will all be in our basements and we will all be on stupid chat lines — it's absolutely ridiculous. What we will be doing is what I'm doing now. We will be meeting new people based on affinity.

It is now the death of distance, and we are no longer prisoners of geography. And we have a chance to do things and to talk to people. As good as the Border Patrols around the world are they cannot frisk electrons at the border. And so we have an opportunity, I think, for a real new world.

I leave you with one thought from John Perry Barlow, one of the savants of cyberspace. Two thoughts from John, whom I've never met by the way, we've only shared e-mail. I once wrote John and said, "I think this is the greatest thing since movable type," and John wrote back, "No, since fire." And then we were talking last January, when I was doing a cover story about policing cyberspace, and I'll leave you just with this last thought from Barlow. He said, "You know, people down in Washington have the attention span of ferrets," and he said, "instead of worrying about how to regulate this new technology, what they should really be thinking about is whether there will be a government in 20 years. Because this technology is so destabilizing, that it will change our lives forever."

Thank you very much.

PUBLISHING ON THE INTERNET INTERNET PUBLISHING: THE HYPE VS. REALITY

MODERATOR
Walter Chavez
Web Developer, iWORLD

SPEAKER
Brad Templeton
Chairman and Publisher, ClariNet Communications Corporation

Walter Chavez: Good afternoon, ladies and gentlemen. Welcome back from a good break. Going right on with our schedule this afternoon, the next speaker that we have is Brad Templeton, Chairman and Publisher of ClariNet Communications Corporation. He has been working for this electronic newspaper, which has been on-line for over six years. He's also been doing publishing on the Net for over eight years, and he'll be talking to us this afternoon about "Internet Publishing — The Hype vs. Reality." The format of this session will be 45 minutes of Mr. Templeton speaking to us, and then 15 minutes of Q & A.

Brad Templeton: I've come to you to speak about publishing on the Internet because I have been doing it longer than most of the people, [and I] certainly have tried it probably as long as anyone. There has, of course, been a great deal of excitement. What I call "The Information Super Hypeway" sprang up about a year and a half ago, when Al Gore got very excited about it, and suddenly everyone thinks that the Internet is the complete revolution in publishing. It's not happening quite that quickly, but a number of interesting things are happening.

I've come here to address some of the experiences I've had in publishing in different ways on the Net, to tell you what things aren't happening that some people are hyping about, to tell you what is happening, and to tell you a little bit of my own hype about what may happen in the future.

I'm going to talk about the way that we publish and the way that a lot of other people publish using the technologies of the Net, such as the Web and UseNet newsgroups. I'm going to talk about how people are charging for information on the Net and trying to make a publishing business, and how they get that revenue. In particular, I'll talk about what they've been doing with advertising and what we do with subscriptions. And I'm also going to talk a little bit about how people who provide information to publishers are paid.

To give you a bit of the background that I have and why I should be listened to about this subject, I've been involved with the Net for a great deal of time. First, I got on my first ARPANET mailing list I think in 1979 — which is way too many years ago — and started bringing UseNet into one of the first international newsgroups in 1981. In 1986 I started the creation of what is still the most widely read thing on the Net, even though I don't do it myself personally anymore: a special newsgroup called rec.humor.funny. I hope that many of you are familiar with it. If you are familiar with newsgroups, and I hope you are, rec.humor.funny was one of the first attempts to try and do something that was a professional publication in the Net world back in the 80's, before Al Gore had discovered the Net. And it consisted of an edited comedy publication.

There are lots of people on the Net these days who love to trade jokes, and I don't think any of you who have an e-mail address haven't managed to have some friend send you the latest joke into your e-mail box. Rec.humor.funny was an attempt to receive the best material; I would pick from my own subjective opinion and send out only two messages per day. This was something that everyone could handle, rather than a hundred messages that were mostly

arguments about whether something was funny or not — which obviously amused you when I described it — but unfortunately that joke wears a little thin. Instead we would give people the best two messages a day, and that actually very quickly became the most widely read thing on UseNet.

Now, are most of you familiar with all the different Internet publishing technologies and know what UseNet is? How many of you are squirreling up your head in confusion when I say UseNet? Okay, that's good, a couple of you.

The Internet is really just underneath a "point-to-point" network, and what really makes the Internet different and what makes it happen are the applications that run on top of it. The people who use the Internet, the people who run these applications, use the Internet as a medium to get data from one place to another. The electronic conferencing application that is most common on the Internet is called "UseNet electronic conferencing," meaning people having electronic discussions with people sending or posting a message and expecting a bunch of people to read it and then respond to it in what are sometimes called "bulletin boards," or "forums" or "SIGs," whatever on the on-line service [calls them].

The Web is the technology that people use to browse and move around through bodies of information. It's not commonly used for discussion; UseNet is the technology that's used for discussion. It also, as it turns out, is interesting as a publication technology, and I'll explain some of the reasons for that later.

Anyway, that quickly became the most popular thing on UseNet. Recent surveys, much to the surprise of many, actually showed that reading newsgroups — at least among the survey body of the most recent survey I saw — is still a more common activity than browsing the Web. E-mail still is the big winner. The Web has, of course, been the big surge; the Web is a newer technology, it's much sexier and it has a number of capabilities that are not found in a system that was designed for conferencing that are also very nice. And there are actually merits to both methods of distributing information, as you'll hear.

I'm also the publisher at a company called ClariNet Communications. Back in 1989, after I saw that these jokes, which was just something that I did for fun as a hobby, became one of the most popular things on the Net, I resolved to find out whether or not you really could make a publishing business on the Net to give people actual professional edited information and see if they'd pay you money.

That led to the formation of the Net's first electronic newspaper, which publishes in the format I just described and is also read on the Web. This electronic newspaper, which we sell into sites, has just passed having one million paid subscribers. It is not free like most of the information on the Web. People get it only by paying a subscription fee, which is a flat fee to receive it.

Both of these, I think, are reasonably good success stories — or at least I like to think so — and because of that I've developed certain perspectives on just what works and what's being hyped in publishing on the Net.

I guess I certainly bought into — and still buy into, to some extent — the basic hype concept that excited everyone about the Net in the early days when people spoke philosophically, and that was this idea that anyone's a publisher, that there is no barrier to entry to publishing, that anyone can write something and put it out and have it be read by a large audience and the result of that would be a content bonanza. If everyone could publish, well, then everyone would publish and all kinds of great information would be out there. And, of course, "content bonanza" is not exactly the right word; having everyone publish turns out to actually create another problem.

It creates what some people call "infoglut," and it creates a great difficulty in finding the relevant information that you're actually looking for. People thought that publishing houses

would be dead. People thought that the idea of having a *Random House* — or even a *New York Times*, for that matter — was something that wasn't going to exist anymore, that with a barrier between the writer and the reader there was very little need for all the great mechanisms and all the dead trees that are knocked down in order to print those things.

Now, I actually agree with getting rid of the dead trees. One of my mottos used to be "It's wrong to ship data in trucks," and I don't need to preach that anymore to the Internet audience. Everyone here pretty much agrees that shipping data in trucks is a bad idea, although there's still a pretty big CD-ROM industry that is shipping the really, really dead trees, since that's what plastic comes from, in trucks. But they're a little more compact, and they've had the benefit of several millions years of data compression, I suppose you could call it.

Another thing that sprung up with the Net, and it's both a myth and true — which I guess makes it the best of aphorisms — is that information wants to be free. There's a large belief that everything on the Web and on the Net is free, must be free, can't work if it's not free, and this has caused people to believe that advertising is the only reasonable model for information publishing in the electronic world. That isn't true, but you'll certainly see a lot of people believing that. Just about every new Web service that I've seen on the show floor here and in other announcements recently has expected that it's going to get its revenue from advertising. People believe that they can put their URL on a shingle effectively — to bring out the old metaphor — and the world will beat a path to their door. That myth actually was dispelled pretty quickly; a lot of people have realized it's not enough just to put up a Web server and say something.

The other myth that certainly is not true, although there are other things to it that are true, is that the Web is the Home Shopping Channel. I must admit to a certain failing of my own here, that the success of QVC and the Home Shopping Network and similar channels was a great surprise to me. I normally think that I can predict what's going to be a good business success, or at least something that's going to become a billion dollar company overnight; you hope that you knew in advance that it would be something. Unfortunately, I don't believe that the Net consists of people who have no lives, who spend their days watching cubic zirconia spin on the screen. And most of the sales of the home shopping channels still, surprisingly, are for the costume jewelry.

It's a very different audience on the Net. They're not going to buy things the way that people have bought on the home shopping channels, but they might buy very different materials and there is still, I think, a bit of untapped potential there. But the simple attempt to move the old styles of television and catalog shopping into the Net are not necessarily meeting with big success. Some things, some more unusual products, are.

Let's discuss the different methods of Internet publishing. (I'd like to have a [lavalier] mic; it kind of makes me stay still when I have to sit in front of this thing.)

The Web is, of course, the current method of Net publishing, and it's certainly the most advanced technology that there are non-proprietary viewers for. Certainly everyone agrees that some of the newer technologies, and even some of the old technologies that could display multimedia data, were more sophisticated than what the Web can do. **But the key, of course, to publishing is — as I discovered fairly early on — you can't try and sell somebody a consumer document at consumer document prices, and tell them, "And by the way, you just have to buy this \$20,000 computer and this \$10,000 software program to read your \$1 document." That's not going to happen.**

But you can instead get a critical mass of people who already have the tools to view the information — and even almost as important as already having the tools, already know how to use the tools. Again, you can't hawk newspapers on the

street if they need a user manual with them in order to describe how to read them. And it's very important, I think, if you're going to be in the business of selling content rather than in the business of selling technology, that you use technology that everybody already knows how to use and hopefully already has.

So the Web certainly is something that's come to meet that qualification. And that, of course, is what has excited people about the Web.

It does suffer from a few problems, however. Everybody knows that the Net is not 100% reliable, that many servers are faster than others and many are quite slow. We've all seen the standards wars that have been going on, companies like Netscape, which surged in early and took the market away from companies — well, not companies, but groups like the NCSA — which surged in early and thought they had the market. They have, of course, tried to do it using all their own techniques. Many people applaud that and say, "Good. You know, standards meetings are a big waste of time."

And I actually have a bit of sympathy for that philosophy. Nonetheless, competing standards will defeat the principle I just described. If your goal is to sell content you really don't want to spend a lot of time convincing people to buy technology in order to sell content, particularly if you're looking at the mass market. If you're looking at selling \$10,000 or \$500 a year in newsletters to people, it's OK if you have to sell a little technology along with it. But if you're looking at just selling ordinary consumer information it's not going to work. People have to have the tool already, and if there are a lot of competing standards then that, of course, goes against what you want.

Everybody knows the example of the compact cassette, and how standardization made that happen when before, with the previous competing standards, they couldn't make it happen.

The other application that is still happening is the dedicated applications, and they have that problem I just described. They include, to some extent, *Acrobat* and the upcoming *Blackbird* application from Microsoft. However, what's happening is that these people realize the exact point I'm making and they're working to see if they can make their dedicated applications ubiquitous.

Netscape made a very bold move, an example of a certain Net phenomena that I'll characterize later, in giving away their browser free in order to get market acceptance for it. When they first came out and said, "Hi, we're going to be a commercial browser company," I said, "Well, that's kind of interesting, but you're not going to get anywhere." And to myself I said, "Unless you've got the guts to give it away free." So anytime someone does something that, [something that] I think is a good idea, I believe they're a genius. And they did do it and they did manage to capture that market share.

They followed an interesting principle, a principle that no one expected to be the case. Those who were on the Net in the very early days knew, at some point, that this was something exciting. Everybody knew that this was the next generation of something. We didn't know what it was, but it was the next generation of something. And we knew that at some point people like Al Gore would discover it and there would be a flood of excitement about it, and everyone felt that this discovery would be about as productive as the Native Americans felt about their discovery by the Europeans.

As it turns out, it wasn't at all like that. What's happened instead is that the bulk of the world has come and embraced the Net and said, "How can we be like you?" This is not what the Europeans did to the Native Americans — at least not until we started making movies in the late 20th century. And this is just a very different phenomenon; it's not like the normal social — the normal conquests, or what happens to anything when the general public discovers it.

Netscape did the same thing. I mean, Netscape's move would have been considered crazy by people in the traditional software industry, to give away all that software. Now, you know, I don't mind if people call me crazy if I have a three-and-a-half billion dollar market evaluation.

Anyway, the dedicated applications do have to face that problem, and I believe they're working on it. I mean, Adobe's original plan, as an example of this, was that they would sell *Acrobat* viewers. Are most of you familiar with Adobe's *Acrobat* technology? It was another attempt at electronic publishing — well it is [electronic publishing], I shouldn't call it an attempt because I think it still has some life in it, certainly. And they originally said, "We'll sell these viewers. We'll sell the filtering tools and the 'distillers,' as they call them." That wasn't going to work, and it only took the big lesson of Netscape to teach them how to work in the Net world.

Nonetheless, if you're going to publish documents, unless you have a very specialized application you need something that all your viewers have. You don't want to tell your viewers, you don't want to tell your readers, what they're supposed to use in order to deal with your documents.

Some people actually think we're a little bit strange because we still use the newsgroup technology. It's certainly a more limited technology in terms of what it can display and how pretty the material it can display is; and its access control facilities, the ability to give information to some people and not to others, are limited to site-based controls. You can't say, "One person gets this and another person gets that." But it's been around a lot longer and it's standardized reasonably well, and it's actually very efficient.

The technology of electronic conferencing systems — in particular with UseNet — is distributed. When messages are posted to a system like this they are transmitted out to all the neighboring computers of the originating computer, and then they share it with their neighboring computers if so authorized, and so on and so on. "They tell two friends, and they tell two friends..." to paraphrase the old shampoo commercial, and that floods the message around the world. And then everyone reads it locally on their server.

Recent technologies have made that very fast so that the propagation takes place in minutes, where in the old days it used to take days, and that had an interesting effect on the caliber of the conversations. But today it's all very quick, and the nice thing is that if you know a lot of people are going to read the information — which is sort of the goal of publishing, at least on a large scale — the information is put into their server in advance, and when they go to access it they get it at the speed of a local area network rather than at the speed of the Internet, without using their own Internet pipe.

Another often-overlooked but still very productive method of information publishing on the Net today is e-mail. A lot of people find it very unsexy when I say that e-mail is still really the killer app of the Internet. People who have not yet experienced having e-mail links with their suppliers and their customers and the people they do business with don't realize what it is. I mean, it's hard to imagine even the days of fax after you've spent a little while in the e-mail world. It's actually overwhelming sometimes, and we need to learn exactly what the right level of e-mail is. But nonetheless, it's still a very powerful application that most of the world has identified, and still the number one application of the Net. And with e-mail, of course, you can control who gets something.

The only real disadvantage it has — well, there are two disadvantages. One is that there's not enough standardization in mailers for sending multimedia documents and doing interactive things. I'm sorry; that's the third disadvantage of the two I was going to list. The

display formats are more limited, and you can't do interactive stuff. But other than that, of course, you can direct information to the people you want, and they'll get it and it comes to them — which is one of the other disadvantages of the Web.

Right now, the Web is something that people have to go out and get; if you want to get a Web page you have to remember that you're going to that Web page to get information, and you don't know — unless you use some rather unusual tools that have recently come out — that a Web page that you're interested in has changed, or that there's new information for you there.

The Web is still a browsing technology. There are some new exciting details, things like *Java* which include the ability to push data out at servers or at clients once they've already made a connection. And if you've ever experienced the magazine *Hot Wired*, most of you may have run across that. *Hot Wired* learned that when they were doing their magazine people would come, look around *Hot Wired*, and then they just wouldn't come back. They figured it was another Web site, and that's what you do with Web sites — you look around them and you don't come back to them. So they figured, "We'll actually e-mail people what the new stories are," and when they e-mail those stories out that gets people to come to *Hot Wired*.

Another reasonably successful — small, but a good model of a small successful electronic publication — is a magazine called the *High Performance Computing Wire*. This particular group of people sends out information on supercomputers, and they e-mail to people all the headlines when they generate them once a week. They get a summary of the headlines, and then the people go back and can query from various servers the stories about high performance computing.

This pushing data at people is what I think is sort of like home delivery as opposed to going to the newsstand to get your newspaper; and that's why we like the technology that we use. Newsgroups and electronic conferencing systems, while originally meant for discussions, actually have a number of facets that are useful for reading constantly changing information, that were meant for reading constantly changing information. So they keep track of what you're interested in, and what you've read, and they present to you what's new that you haven't read before.

Again, that's something that the Web doesn't do, although I'm sure it will do at some point in the future.

File delivery is sort of the last and probably the oldest of the methods of electronic publishing. It's still being used by a few people out there. You will find that some people — for example if they do have a very customized piece of information — will simply send you a file, and you'll drop the file into your Windows system and you'll click on it and then you'll get some kind of interactive application that gives you information. And that obviously, in the end, can be very flexible, because you can send someone programs as well as data and, assuming they trust you, you can send them programs that actually do things. But on the other hand file delivery is itself pretty cumbersome, and as yet there's no real easy way to just nicely shove files at people, simply because of the trust issue. People are not just going to randomly run files that come in from anywhere on the Net.

Multimedia have, of course, excited people. (I got to just use "media" in the plural, and that makes me very unusual.) Pictures and graphics are necessary to really excite the general public, and for them the Web is the most advanced technology in displaying that sort of material.

The problem, of course, with using that on the Web is that if you want to do really serious pictures and graphics you run into a problem, because of the speed of your own lines and also because of the speed of the lines that the customers and readers are using. There are just too many people in there who are still using 14.4 modems; and it astounds me, actually, to

see the Web pages that some people put up. They put up a 90KB graphic — and I have a T-I, it's a very nice toy and I think it's a lot of fun — but I just can't imagine how people are reading that sort of material on slow, modem-based links.

The nice answer to that, as has always been true in the computer industry, is that being too big and too slow is a problem that hardware fixes for you if you wait a little while. In fact, in the very early days of the computer industry I remember a number of friends of mine who made themselves quite rich by writing programs that no one would possibly want to use, because they were impossibly slow on the current hardware — and a year later they were the only ones who had an application, and it happened to run okay on the hardware that they had, or it came out later. So let's not deny the value of that.

Graphics are going to become cheap, and particularly if standards develop. There are also a number of standards that are better at sending non-photographic graphics than the ones that are used currently.

[My next point is about] video. I definitely think it is a toy right now. Video compression technology is not nearly good enough to be used with anything but the really, really fast lines that are out there. You will find Web sites that will download a video to you, but I don't see people practically publishing video to people any time in the near future. That needs not just slightly better or twice as good bandwidth or twice as good hardware for communications; it needs orders of magnitude more improvement.

Of course, there are people who think that video is the only purpose of the "Information Super Hypeway." When it was first announced, many people announced their vision was 500 channels. This is what we do with all this, this great data network that we were going to build — give people more TV. My expression of that is that's kind of like the horse breeders back at the invention of the internal combustion engine reveling at how much faster they can ship horses to people. I certainly hope — and when I talk about advertising I'll tell you a little bit more about why I hope — that TV isn't the model of the information world of the future.

[The next topic is] sound. When I've wandered the show floor here I've seen a lot of people that are very excited at the sound-based companies that are out there. I still am a little bit unimpressed, because again, it's sort of like the talking dog. I mean, it's neat that you can do it at all, but the sound technology isn't very good for most people. I don't think I have to do phone calls over the Net.

The sound bandwidth, however, is probably the first multimedia thing — after graphics — that's going to come within range in a very short amount of time.

On the other hand, I happen to think that sound for publishing is not all that exciting. When it comes to news, which is my business, you're not going to really be hearing someone say something; it just doesn't add that much to it. I mean, radio has a purpose. Radio is there when your eyes have to be somewhere else, when you're driving or when you're jogging or something like that, or you're working around the house. And radio will never die because there will always be environments where our eyes do something else, and we would like to be informed or entertained.

But when we're actually staring at something, the truth of it is that sound is sizzle rather than steak. And while I'm sure people will include it and I'd like to see things done with it, the truth is that the meat of the matter is not going to come from sound.

Text, on the other hand — all the media do that great. We've certainly started with text, and we did nothing but text, nothing but plain text, for the first several years. We only moved a year or two ago to doing things like comic strips and photographs and stuff like that.

You have to decide, when you're doing this decision about all the multimedia aspects that you can publish, "Are you selling steak or are you selling sizzle?" That's not a facetious

question. A lot of people, a lot of publishers and so on, are just selling entertainment, and what they want to do is give people some sizzle and make them feel happy.

There is real content in *Wired* magazine, and it's just in the wrong color. Perhaps some of you have seen a new magazine called *The Net* — if you could figure out that was its title. How many of you ran into it? My description of this was a magazine for people who didn't think *Wired* and *Mondo 2000* were garish enough. So there seems to be some demand for sizzle here in the Net world.

Why do we use UseNet technology? Because it is the older technology and doesn't have as much sizzle to it — although today you can do multimedia stuff and it can be read by the most number of tools. It can be read by all the UseNet newsreaders, and there are lots of them that are free. There are a number of Windows and Mac-based ones, some of them as commercial products. And while not everyone knows it, there's actually a pretty decent one inside *Netscape*, which is of course a Web browser.

In fact, they've actually put a lot of effort into it, as you can see if you've looked at the new beta version of their next release of *Netscape*. They've actually decided to make the newsreader a very specific and special-effort, extra application that runs inside the *Netscape* environment. Maybe *Netscape* will — what was it that someone said? This is actually true. Someone once said that in the old days of UNIX every program expands until it can read mail. And that's already true of *Netscape*, so maybe we'll start seeing that every program expands until it becomes an operating system, which is where *Netscape* certainly seems to be going.

One of the main things that I think is important — and I argue with people about how important this is — I'm a speed freak. I believe that everyone, once they're given speed, is a speed freak as well. How many of you remember how excitingly fast you thought your 2400bps modem was? I certainly thought it was great, and you couldn't even stand to touch one today. So once you're given speed, you want it. And I like the idea of putting the information in advance into someone's machine; because you know they're likely to ask for it, so that when they do ask for it it's there. Once you have it you can't go away from it; you can't sit there and watch a little meteor shine past that "N" for twenty seconds. I mean, do I detect that other people are tired of watching that meteor go by? Just a guess.

No, obviously you can make the meteor go a few less times with faster servers and faster bandwidth, but nothing beats having something on your own Ethernet; and that's one of the reasons that I think that pre-feeding the information has a lot of value. If your people are going to really use it, really go through it — I mean, there are people who are information junkies, some of them our customers, and I think the early adopters and the people who talk about stuff are definitely these kinds of people. And the ability to go bang, bang, bang through information is not to be underestimated.

As for pictures, and I suppose eventually for video and those other multimedia things, it's a real difference. We've decided to — I try not to plug too much in talks, but I'll plug it here — which is to say that one of our announcements at this show is that we're doing wire photos with the news, and that they look very nice. We've decided to release them in two sizes. One is a modem-type size, a 9KB picture that you can download on a 280 modem in just a few seconds, and the other one is about 60KB or 70KB and really looks good.

My impression is that strictly because it's in color, if it's not really big it hasn't got more resolution than a newspaper picture has in terms of hard pixels; but because it's in color and it's on a decent screen, I think it actually looks better than the same picture in the newspaper. But it needs to be about 60KB, which just isn't practical at all for someone who's getting it over a modem, or for that matter even over a 56KB ISDN link.

On the other hand, if it's on your LAN you can get it as fast as your computer can render a JPEG, and that makes a big difference. Photos are a little bit more sizzle than they are

steak; they have some information in them and they're useful, but when you get a picture up — zap, on the screen — or a comic strip — zap, on the screen — it makes it something you'll really do rather than something you'll play with.

And while most people at this conference won't admit it, right now the Net's a toy to most of the people who are on it. People are playing with the Net and there's... Look, there's real information out there. You can get Dun & Bradstreet reports and you can get stock quotes and stuff like that, and a lot of people are using those. But there's a lot of people still playing, and if you want people to seriously use it you want to give them all the speed you can.

The other reason we use it is that — at least according to that survey that I read recently and some other information that we have — it's about as popular as the Web, maybe a little bit less, maybe a little bit more. And it's also, as I mentioned, a medium of sending information to the user, home delivery rather than going to the newsstand.

News is supposed to surprise you. A lot of people think that the ideal electronic newspaper of the future is a mechanism that they go in and browse and they enter a keyword and they find the news that matched the particular keyword that they're interested in. That's actually something that's existed for a long time. The on-line dialogue and Nexis database services and several others have done that for some time.

I believe one of the things that we value about news is that it comes at us and that it informs us about what's going on in the world that we didn't even know about, that we didn't know we were interested in. And to do that, it has to come at you. And I think that's very important, and this is one of the things that technology does.

It turns out that this technology, because it was simpler, only allowed us to control what site would get something, so that we can say, "This site." You all know what I mean by a site? It's not an individual Windows workstation, but it's actually a LAN or a server computer, the dedicated server computer — or not necessarily dedicated, but a computer that's up all the time and typically running a multi-tasking operating system, like UNIX or one of the other various multi-tasking operating systems.

I suppose Windows NT also has a number of such server tools for it now; the Macintosh, unfortunately — as I often say about Apple, multi-tasking was only invented until about the mid-60's, and I think Apple will get it ready some time in the 90's, if they actually get around to it. It's true. I mean, they just don't multi-task very well. And it's sad, actually, because there are a lot of good things on Macs, and a lot of people run Macs and it would be nice if they could do those things.

A site is a group of people rather than one individual. I think this turned out to be, while initially perhaps thought of as a limitation of the technology, a right move from a business standpoint. It was a good idea, and I'll explain why.

UseNet is still the community of the Net, something that is realized by those who are involved, but not necessarily realized outside. Even people who are designing Web applications use newsgroups and mailing lists to some degree to discuss exactly where the Web should go. The Web is a neat environment for browsing and shifting around through information. It's not yet an environment for discussion, except with a few specialized environments in places like *Hot Wired*.

The revenue model that we follow is subscriptions. We do not take advertising at this time. We sell subscriptions, however, on a site basis. And the reason that I said we were sort of forced into that decision — and it came out to be a good idea — is because so far we're not seeing any reports of — we're looking around, and that doesn't mean that our search is comprehensive — but we're not seeing any reports of people making a lot of money with individual subscription sales of Web services. Which is to say, "I have a neat Web site with content or whatever else it is, and if you pay me \$5 a month or one penny a hit, or whatever it

is that you want to pay, you can get access to my Web site.” There are a number of people who are offering services like that.

A number of the other electronic news offerings are working that way; there are people who will give you stock quotes, there are people who will give you all kinds of other information sources, and the truth is that their subscribers still number in the low thousands at the very best. None of them are profitable businesses unless they have very, very low costs at this time.

We also feel that there is a problem with subscription Web sites because I think there’s a limit on just how many sites a person is going to subscribe to. I mean, you’re not going to realistically maintain the bills from 30 different Web sites or pay fees to 30 different Web sites or, in the current technology, remember passwords for 30 different Web sites. And that’s probably one of the barriers that’s interfering with people doing subscriptions in that sense.

Again, the Web is something you have to go out and do rather than it coming to you. It’s much easier with magazines to subscribe to 30 magazines, although most people don’t subscribe to that many. The password system they currently have turns users off, but I think that that’s a technology thing that’s going to be fixed.

The winner for us has been site-licensed subscriptions, and that’s for several reasons. I think one of the key reasons it’s been a winner is that it really mirrors the way the Net worked and what made the Net a success, and that was flat rate pricing for everyone. The thing that made the Internet different from all the other Nets that came before it was that you, your company or somewhere that you were working, paid one flat amount of money; they got a connection and then everybody was told, “Go play. Do whatever you want. Use as much as you want. Use as little as you want.” Some people will use a little, some people will use a lot, and it won’t cost you any different depending on what happens. This caused people to go out and say, “Well, you know, I’m going to put up an FTP server and I’m going to serve up files for people.” And they came and they really liked it, and it became a positive thing.

In the old days, when people had to pay as they played, if you were to put up a file server on, say, the old X.25 network — which really had all the capabilities, in a way, in terms of one computer being able to talk to another — if you were to put up a free file server your boss would fire you. “You’re causing all this traffic on our network, it’s costing us a lot of money in packet charges. Go away.” And things like the Web server just would never have been experimented with.

The idea of a Net where people could play and experiment and not have to pay different amounts of money caused the Net to happen. It caused people to design the Web and the Web protocols, and caused people to put up neat Web servers, and narcissistic Home Pages and all the other things that made people excited about the Net.

Well, on the other hand, this site license principle works very well, and it’s what people on the Net are used to. And like the Native Aboriginal Americans being discovered by the Europeans, the outside world’s marketing rules don’t always work on the Net, but site license does work on the Net. It’s what people are used to. It’s how they pay for things on the Net.

We think that the opposite technology is “micro-transactions,” which is my word for what you see from the various digital money schemes. Many of them advocate — not all of them, but many of them — advocate the ability to buy this document for one-tenth of a cent and this document for two cents, and this document for five dollars, and just go around and pay digicash or cybercash or some amount of money for that. I don’t think that’s a good model at all for the Net, and I’m not sure how I’ll go into it.

The thing that I think actually is going to be the successful model is bundling of services together. I think that you need to have a lot of different services. One of the things that we think has led to our success, rather than an individual wire service like Reuters trying to sell its

data to the Net and getting people to come in and pay money either in subscription fees, micro-transactions, or through ads, is that we put together six or seven different wire services and combine their information in the same way that newspapers did, the same thing the wire services do, in just about every town in the world.

People are much more willing to pay for lots of different premium information sources. Then we divvy up the money and pay royalties to the people who provide us that information, and we think that making that bundled package gets people very happy, and they buy our service where they wouldn't necessarily buy the individual services one at a time.

Cable TV has, of course, been based on the same model, and several people in the on-line world have also worked in that model. The only reason they've stopped doing that flat-rate bundling is because it was too successful, and it got too many people and they had to pay a lot of costs to maintain their systems to do that.

Now, there are a lot of ad-supported Web sites out there, and that seems to be the model that's excited most people. I haven't talked too much about it. We don't take ads, as I mentioned. It's not that we really think that we couldn't have made some money from ads. I think that if advertising becomes a big successful model, then it won't really be that hard to find out who's advertising with other people. Unlike secret client lists, you kind of have to advertise this one. So that doesn't scare me too much.

I'm a little bit scared at the idea of the Web becoming like television, that if advertising is the only way that content is supported we'll only get the kind of content that advertising supports, and that concerns me a little bit.

But nobody really knows what to charge for advertising. Right now all the advertising on the Net is "let's see" advertising. It's not, you know, the old style advertising in traditional media that has been around for a century, where people say, "Okay, this ad cost me \$3,000, I got 2,000 leads from it, 500 people bought something. I'm going to buy that ad again." That's not happening on the Web right now. People are saying, "We'll buy an ad and we'll find out what happens."

And that's interesting, but it's not a business yet and nobody knows what to charge or even what they're getting from it. Some of the ads that are being sold on the Web right now have ridiculous CPMs — that's an advertising term meaning "cost per thousand people who are exposed to the ad." Prices are way beyond some of the media, which traditionally have been very good media, and it's a little bit of hubris to suggest that the Net will support that level of cost.

Just a side note is that classified advertising is the source of 40% of newspaper revenue approximately in the United States, and thus one of the most significant types of advertising in the world. Yellow Page advertising is also classified advertising, and also a very significant revenue source that obviously isn't something that can support content very easily. And it's also, I think, something that's going to become free, like e-mail is today. It's just so easy to do; but I'm not sure that people are going to make a lot of money from it.

Let's go fairly quickly because I do want to get to your questions.

Web ads, if they're going to be successful for anyone, are going to be better for the little guy. I mean, frankly, I see Sun ads on Web pages that I go to, but I sort of already knew who Sun was. It's no question that big companies still advertise and like to push their name in front of people lots and lots, but I think actually the Net, because of the eclectic and rich audience it gets, is probably going to be the bargain more for the little guy who no one has ever heard of, and for the person whose link you're going to click on because you're actually interested to know what they're doing as opposed to the companies you hear about all too regularly through other means.

It is successful right now to run a Web site that's an adjunct to another business, which is to say if you already have a business and you want to promote it a bit, you're already publishing something and you just want to make sure people know you're publishing it. That's a success.

I want to get some of these later points, so I'm going to gloss over these things.

People who love the ad subsidies — my disaffection for ads is probably not going to be recognized in the general public — probably do want the Net to become like television; they certainly wanted television to become like television, so I'm not sure how successful we'll be at pushing away the evil forces of advertising, but I think the Net is probably an environment where it can happen more than it can on television. There are technological ways to do non-advertising-based content on the Net, and there aren't in television, not very easily. And the few that are [in television] are cumbersome, and Pay-Per-View has never been a big success.

Of course, the other difference is that people are learning the difference on the Net between ads that bother people and ads that attract people, and they're realizing that ads that attract people are the only ones that work on the Net. That's pretty positive.

I mentioned micro-transactions, and I think they're an enemy of the Internet in a way, because I believe that the Net was based on this idea of the flat-rate site license pricing. I don't think people want to have a meter running. Most of you live in areas where you can get unlimited phone service or you can get per-minute phone service, I guess. And how many of you get the per-minute phone service for local calls if it's an option for you? How many of you, one, two people? And how many of you make more than, I don't know what the number is, three to four hours of local calls? How many of you who get the unlimited service make three or four hours of local calls every month?

Well, more than I would think. In the place I live the local calling area is very small, and it turns out that most of my friends aren't in my real tiny local calling area, so I still buy the unlimited-rate local calling service because I don't want to pay per minute. I'm not poor, but I don't want to. For some reason, I don't want to pay per minute or pay a penny for every minute that I'm on the telephone when I happen to be making a local call.

It turns out that about 85% of people buy unlimited local phone service, and for about half of them it's a bad buy. The phone company prices it at exactly the point where it will be a bad buy for about half of them, because they want to collect exactly the same amount of revenue when they have, in fact, these deals with the PUC to make sure that they collect a revenue that goes over their costs by a certain margin.

People seem to like that when it comes to consumer electronic services. They don't like micro-transactions; they don't like a meter running all the time when they're doing things. The CompuServe and the AOL way of things is to have a meter running, although even CompuServe and AOL know that [by having] the flat \$10 fee for about half their customers, which about half their customers never go over.

So flat fees made the Internet what it is. Oh, another little hype thing that I would like to mention is this big belief that is prompting the existence of all the security firms on the Net floor, or at least all the people who want encryption of stuff — [the belief] that credit card transactions over the Net are a huge risk. What no one will admit is that there's never been a documented case of someone having their credit card sniffed while it went over a Telnet session or a Web page forum and then having something charged against them.

Because of that, there are stories of people's credit cards being stolen from databases where they were found on the Net, but not packets wandering around over Ethernets and over Net connections. I have given my credit card number over the Net and have had no problem.

The truth of it is — most people don't know it I suppose — but you can invalidate any credit card charge that isn't signed by you anyway. So if someone takes your credit card

number and uses it you do have to get a new credit card, which is annoying, but you're not out any cash. The bank, on the other hand, is very interested in the encryption. The reason is left as an exercise to the reader.

[Tape change]

Brad Templeton: I wanted just to avail people of the idea that in the new electronic publishing world of the future, royalties will be 80%. Some people actually come up and suggest that to me, saying, "What are you doing? I mean, you're not printing. Why should you get the publisher's share and I get the author's share?"

The publisher is not just a printer. A lot of people don't seem to realize that. The elimination of the printing press is not the elimination of all the work that the publisher did. It does eliminate one of the costs, and so royalties can increase.

But the truth of it is, if you look at the publishing industry, the old paper industry, a good rule of thumb that was very common in a lot of publishing houses is that the author's royalty and the publisher's net were about equal. If an author got a royalty of 10%, that's pretty common. And the publishers would make a net profit usually in the 10% range.

So the truth of it is, you can take out the printing, you can take out the distribution, you can take out the retailing and all the different things that you take out; but the truth of it is that the publisher, the work the publisher was actually doing, all that other stuff was always jobbed out in just a cost. The work that the publisher was actually doing still needs to make that same amount of money, in terms of promoting, getting material in front of people, identifying the best material so that people will not have to hunt through and search; all these things still need to be done, and publishers still need to do them. So they're not dead in spite of the hype that they are.

We're still working out what royalty percentage actually is the right one. Some of the royalty percentages from print publication are pretty dismal, mostly because there are a lot of writers who will write for the love of writing rather than as a business and so they'll take a 6% royalty on something. And that is a little bit low, I think, even with the economics of print publishing.

I think those rates are going to go up, but they're not going to become 85%, for example, which some people actually run around and suggest as a royalty. That's actually what your agent gets if you're a writer — you give your agent 15% and you collect 85%, and the agent doesn't do anything but make the deal. Making the deal has its value, and its value is pretty well established, and many people think that agents are a bargain. My father is a professional novelist and he thinks the agent is — well, he's older, so he thinks the agents it the best 10% you can ever spend. But I think he'd still agree an agent is the best 15% you can ever spend.

What am I going to skip over here? Some of the things that are going to come, new trends in publishing. I think that the existence of links inside news is actually going to be a very important, exciting thing. We plan to work on it. I think they're going to create a revolution in journalism, because journalism is typically full of errors — not because reporters are malicious or bad, but simply because they're people, and they have biases. I mean, there are biases in all stories as well, but I think links [exist] inside stories, so that when you read a story about something that happened at the White House you can follow a link and read the White House press release, and read the statements by the people who are mentioned in the story, or that the person mentioned in the story can write the reporter an e-mail 10 minutes after the story clears, and say, "You know, you spelled my name wrong, or you did this or you did that." And if

it's just an ordinary error and not something deliberate it will get fixed, and I think we're going to see remarkably more accurate journalism as time goes on.

I think, also, that publishers are going to start thinking about doing services as well as content. They always did, but they never really thought of it that way. And you already see some firms out there like Excite and McKinley and Web Review and so on who are publishing information about the Net, but they're also sort of helping you find things on the Net. They're being guidebooks as well as just sources of information.

I'm going to skip a couple of these points and just go on to say that, unfortunately, I'm not yet ready to talk about what I think is the final answer to the question of how to make non-advertising-supported content work on the Net. But I do believe I have an answer based on my history in the Net, so I will simply tantalize you by saying that if you are a content publisher wondering how to sell content on the Net, live within the spirit of the Net and not have to rely on advertising, come give me your card and I'll contact you at some point in the hopefully not-too-distant future.

This is a complex industry, and I hope I've covered some of the points for you and some of the experiences we've had. We have about 10 minutes, I guess, for questions. Yes.

M: So, about pass-along problems. You've obviously had some problems with that?

Brad Templeton: Well, in terms of copyright? Yeah, a friend of mine, [John Perry Barlow], wrote an article which a lot of people have quoted in *Wired* magazine. He said, "Copyright is dead." And I got a mid-seven figure revenues. So it's not dead; I mean, the Net is there.

There are people who pass information along. One of the solutions we have to that problem is we don't sell articles, we believe we sell a newspaper. We don't want people to steal individual articles, because in the aggregate that affects us and hurts our business; but the truth of it is that the main thing we have to focus on from an enforcement standpoint is the theft of the entire newspaper and service. For someone who only wants to sell a single article, that's not a great answer.

Although, however, if you bundle yourself... That's actually a reason why everybody being a publisher with a shingle is a bad problem. A publisher can withstand a single piece of stuff being stolen; if the authors are all being compensated on the total revenues of the publisher, it actually works out pretty well.

The truth of it is that people actually — while they have a lot of disrespect for copyright, they're not wholesale about it. I mean, there are people who have no care about it, but by and large most people seem to know what it is and they're working within reason.

You know, sometimes there are some industries that are hurt pretty badly by copyright, and there are some things that need to change. But by and large it's not the problem that everyone has been saying so far.

M: How do you describe problems like the [inaudible] reader just put up a Web site, and now it's gone down and they changed the focus of it? And do you see magazines building themselves on the Web?

Brad Templeton: Well, magazines are an interesting question. One of the things that we discovered pretty early on in the news business was that yesterday's news was yesterday's news, and that reading on-line actually isn't preferred by most people to paper yet.

There are some people who absolutely just prefer on-line. If you look at my desk, you'll know what I prefer. There's just a mess of paper that I can't, I don't want to deal with. And I fire employees who give me paper, but the truth of it is that if it's weekly stuff or monthly stuff

people seem much less inclined to want to buy it on-line than wanting to get it on paper. So magazines, I think, have a harder road. As I don't know exactly why *Utne Reader* went up and down, as far as...

M: It seemed like it was two months and it was gone. Or the format they were going after was gone.

Brad Templeton: Did they give a reason?

M: They just said there was not enough interest. That was the only answer I heard back.

Brad Templeton: Yeah, I mean, in the case of *Omni* magazine, which made the big decision to go the other way, the sort of unspoken secret in the publishing industry was that the magazine was losing money, and when newsprint prices went up they said, "Can we make a nice PR spread as to why we're shutting this magazine down?" And so they said, 'Oh, we'll take it on-line, and we'll be bold and futuristic.' And — at least in the arm of the business that doesn't have naked women — they're probably going to be a success on-line.

Back there.

W: Your comment about micro-transactions, [inaudible] local phone service...

Brad Templeton: Yes.

W: But see, in Europe we pay everything. We get a flat fee and we pay for every minute you talk.

Brad Templeton: Do you like it?

W: No, but [inaudible] and the way in Europe where people are attached to this micro-transaction model...

Brad Templeton: I think it's going to impede the progress of the Net in Europe and in the other countries where people cannot get away from that model. It's true that the critical mass built in the United States and Canada and the other countries where flat-rate will help. People in Europe will adopt the Net just because they — because it got forced down their throats, rather than naturally, the way it was adopted in other places.

But we've had the ability to do measured-service networking for a long time; that's what the on-line services were in a way for many years, and that's what X.25 was. There were X.25 networks in the 70s, where you could go and make a connection to a wide variety of computers and then you could pay per packet to log-on to them, and it only got used for business use, where people really weren't looking the costs too much. Although, frankly, businesses do look at the cost, and businesses really love to know exactly what something is going to cost them, so they don't really like being billed by the hour either. They just pay it because they have no choice or because they're working on something where they must get what they're getting no matter what the cost, as long as it's within reason.

W: Yes, is the [inaudible] going to ask you about why you think the calls on the Internet are evil?

Brad Templeton: Oh, they're Satan. The reason that they're evil is exactly for the thing that I just described. The Net created a wonderful cost benefit breakthrough because of the idea of sharing a connection among a large number of people to do what I call "long-latency" transactions, where you don't care whether or not your packet gets there in a tenth of a second or a second, or in some cases a minute. You know, if you're sending a piece of e-mail you don't care if it takes a minute versus five seconds. And so you can have a data pipe, and a thousand people can share a 56 kilobyte data pipe and probably send all their e-mail with it, and because if there happens to be too much congestion for a little while we just delay this e-mail by five seconds, by ten seconds, and it's not — for Web pages, you're a little more eager for fast response, but by and large you can wait a tenth of a second versus a twentieth of a second, or versus a second, in order to get a Web page.

Well, voice isn't like that. Voice is "I must have that packet now." It has to get here within — if it doesn't get here within a certain amount of time it's no good, because it makes a disrupted and broken conversation. And there's already a highly competitive voice telecommunications business in the United States.

Now, you're right, over in Europe and in a number of other countries, there isn't a highly competitive voice telecommunications business. But this business — for stupid FCC regulatory rules — is already quite competitive and the prices are quite fair, and they're based on the idea that unlike a data pipe for mail and so on, the sharing is much more regulated. It takes about 13KB with compression of bandwidth in order to send audio along, and once you get enough conversations in it you don't get too much more sharing from taking the silence out. So if you want to have a hundred people share the pipe, you've got to have a hundred times bigger pipe.

So what they're trying to do is when they say, "Talk on the Internet for free," is they're trying to save money off an already highly competitive business, a business which has never managed to make flat-rate pricing work, partly because of the FCC regulations, but for other reasons as well.

And they'll drive the average usage up. When you have flat-rate usage like that, you have low volume users and high volume users, and they share the pipe and the price goes somewhere in the middle between those low and high volume users. If you start pushing everybody to use high volume just so they can save on their phone bills, well, they aren't going to save on their phone bills, the real cost is going to be translated into the average price that everyone pays. So those people who want a cheap phone call will end up making the price of all our Internet calls increase — or worse, they'll drive people to do per-packet charging on the Internet. which will change it from what made it what it is.

M: [inaudible] I was wondering what your thoughts were on those?

Brad Templeton: Well, the main focus of the talk was on publishing, and MOOs and MUDs. You could consider them publishing in a very abstract sense. But maybe the people, the MOOs and MUDs, are an addition, and I don't play them. No. I've heard sad stories about guys who get off trains at stops because they know there's a terminal there and they can play for five minutes until the next train comes. I mean, it's ridiculous. But it doesn't have a lot to do with publishing. I think they're a neat, interesting phenomenon, and they're an interesting type of interaction. But that's really a whole other panel, just about highly interactive technologies like that.

M: What would be an example instead of the [inaudible] successful?

Brad Templeton: Most of the on-line services. Genie is the one I'm most familiar with, but Prodigy to some extent, too. Remember Prodigy's initial business model, which was to be entirely flat-rate and provide all this stuff? The thing that killed it was they didn't realize that people wanted to do bulletin boards and e-mail. They thought everybody would just suck at the Prodigy teat, and they designed their whole network that way. So when suddenly everyone wanted to e-mail and do conferencing, and it all went back to the central network in New York, they found that they had too much load.

Genie and CompuServe, to some extent, ran into that. Genie decided to price their product with flat-rate for non-computing services and an hourly rate for computing based services, and it just started swamping their servers. The servers just went nuts. And they finally decided they just couldn't do this anymore because it's too successful, too successful in terms of what the customer wants. Unfortunately, not too successful in terms of the dollars.

We can take one more question. One there — well, geez, sorry, I saw him first.

M: Do you think the large [inaudible]?

Brad Templeton: Well, no. That's what the Net changes. I mean, the truth of it is, as I said, that people are not willing to just take random content shoved at them from all directions. They really are going to have people as a filter in between them and the information. But they'll have a lot more choice of that, I think. And the large content providers will discover that if they dissatisfy their customers, there are ways that the barrier to entry can be smaller for someone to come in and mention it.

The other thing about the Net that's really great is that if you do anger your customers — well, it's not great when I anger my customers — but in general, if someone angers their customers the customers have a feedback mechanism. The very thing that we're using to publish information to our customers is also a feedback mechanism, to make sure that our customers know what we're doing badly — and of course, so that our competitors know what we're doing badly, unfortunately.

All right. Well, thank you all for coming. And if you need to speak or find out more, I have a booth downstairs.

INTERNET FINANCE FINANCIAL SERVICES INDUSTRY ON THE INTERNET: OPPORTUNITIES FOR YOU

MODERATOR

Timothy Duncan
President, Duncan Resource Group, Inc.

SPEAKERS

Giles McNamee
Senior Vice President, First Albany Corporation
Jonathan M. Guerster
Director of Financial Services, Open Market, Inc.
Richard Moorman
Assistant Vice President, Electronic Commerce, Banc One
Mary Ruth Moran
Senior Vice President, Electronic Marketing, Fidelity Investments

Tim Duncan: I'm Tim Duncan and this is Financial Services on the Internet. Welcome to Internet World. There's a lot of folks here. We've got a couple hours here this morning, and we'll take a break after the second presentation and then we'll do questions at the end for all the presenters. We've got three tremendous, actually four tremendous companies represented here today, as well as mine. Fidelity, First Albany Corporation, Open Market and Banc One. They're all companies that have been very innovative and very progressive in using the Internet, and they're going to share some of their experience here today to hopefully help your companies move along in your efforts in the Internet.

I think that of all industries out there, with the possible exception of publishing, there's no other industry other than financial services that will be impacted quite so heavily by the Internet and interactive technologies. It's the largest service industry that exists. It's an industry that lives and breathes and dies on information, as I'm sure you all know. And it's a very competitive industry, as I'm sure you all know today too, that demands cost-effective delivery systems.

The Internet presents tremendous opportunities for financial service companies to reach clients directly in new ways that present enormous opportunities to develop in a completely new marketing channel, sometimes even to replace what before has been very expensive personal selling channels. And it also presents an opportunity to cut delivery costs significantly for financial service companies.

I don't know how many of you in the audience have had a chance to read Nicholas Negrepon's book, *Being Digital*. It's an interesting book at least if nothing else, and I would recommend anybody that's interested in the Internet, pick it up and take a look. One of the things he talks about quite a bit in the book is the wasted resources in the United States today, and all over the world today, on devoting the conversion of information, which is in electronic form or bits, to paper form or atoms. And I would say that if there is any industry that commits this wastage of resources more than any other, it's probably the financial services industry.

I think all of us, in whatever specific segment of the financial services industry we happen to be in, don't have a hard time thinking how much of computer-based information is translated into paper-based information and reconverted to bits at some point, based on some feedback, and then reconverted to paper information.

Even in that regard a lot is even discussed about security on the Internet today, which is important. But I think a lot of us overlook the fact that on our paper-based, hard transaction-

based systems today, check fraud and credit card fraud alone amount to over \$13 billion a year in the financial services industry.

So any of us who have been involved in the Internet in the financial services for any period of time realize that there's tremendous potential to use these new technologies to change our business and to deliver our services in a different way. And I think a lot of the time... The hardest time I have, as a matter of fact, is trying to figure out what areas that are really where we should spend our time because the potential is so enormous in so many different areas that it's almost mind boggling at times.

On the other hand, the last time I was at the World Trade Center for a show was 1990, and that was something called "DECWorld." And the hoopla was probably equivalent to this. And I remember the day after the show ended and picking up the *Boston Globe* and reading in the business section that DEC had announced their largest quarterly loss in the company's history, and one of the largest quarterly losses in United States corporations' histories, which I thought was sort of a bad timing for them after just having spent I don't know how many millions of dollars on "DECWorld."

The expectations of the Internet are going through the roof, and I don't think anybody can quite predict exactly what's going to happen despite the money that's being made now and by various people in making those predictions. The Internet is still too complex to use for most people. The numbers get bandied about that there's 20 million, 30 million, 40 million on the Internet, but as my mother used to say to my brother, "You know, finish your food. There's 40 million people starving in Africa." And he would say, "Name one." And I think if you get out of the Internet world, the folks like us that are in this thing everyday, and start asking people, "You know, do you use the Internet? What does it mean to you? How are you using it?" You'll find most people are still baffled and reluctant to even to look at it in many cases. So there's plenty of challenges that lie ahead.

Peter Drucker, the management guru, has said that for a new technology to supplant an existing system, the new technology has to be ten times more effective than the existing system for people to basically change the way they do things. People like to do things the way they're used to doing things. And I think that's really the challenge. We [can't] simply replace existing systems with this new technology, expecting that if we deliver equivalent services people will adapt to it. The services are going to have to be much better. And that's the idea today, to help you do that in your own, in your own companies.

We've got three segments of the industry represented; mutual funds, banks, and the investment banking industry. And we're all going to share a little bit of our experience and hope that it helps you.

First I get to do a bit of an infomercial on my company. It's called CorpFiNet. We're a site on the Internet that's devoted exclusively to commercial and corporate finance. Our idea has been first to build a directory, a comprehensive directory of reputable established companies that are on the Internet, where people can access services and products that they need through our directory. We have the hyperlinks obviously, and then we add some content to the hyperlinks. We're going to be soon publishing information and articles on the site with securities data. We're going to be publishing by mid-November, weekly IPOMNA activity around the world, lists of what transactions are being done, descriptions of those transactions, and then monthly and quarterly reports on investment banking and activity around the world. We're going to be publishing a series of articles and interviews on what's happening in the world of interactive technologies and finance. And then eventually we hope to be originating transactions through our site of different sorts, particularly in delivering different types of information.

The services that we offer are basically to help financial service companies use interactive technologies correctly and profitably. We do consulting and help with strategic partnerships for financial service firms. We do Web site creation and management. And we help people in the financial service industry start to learn how to deliver their products and services on-line.

In terms of philosophy in working with people, financial service companies that are considering using the Internet, we have a few ideas that I'll share with you.

The first is that despite the hoopla, there's going to be few revenue rewards from an Internet presence for the next year and a half to two years. If your revenue increased by 1% to 5% in the next two years, I would say you would be very lucky as a result of your Internet presence. People just aren't ready to buy. They aren't ready to spend money on the Internet, and we don't see that happening anytime soon, outside of spending for Internet-related products and services and technology.

It's important when you are thinking about what you're going to do on the Internet to start with a list of objectives. What do you want to do? Are there certain processes that you want to automate, put on-line? Do you want to try and generate new customers? Do you want to originate leads? Figure that out before you start spending money.

We believe people should start small. We feel that the initial expenditures on gaining an Internet presence will probably be dwarfed ultimately by what it's going to cost you to stay on-line and improve your site, and develop new areas in your Internet presence. We estimate that whatever you spend on your Internet presence initially, if it's X, you're probably going to spend 4X a year in maintaining that presence at least.

It's important to learn as you go and build on success. I don't think anybody knows exactly today how things are going to turn out. I think it's important to begin with a smaller site, a smaller presence, figure out what works and build on that success, rather than investing a lot of money in things that may not work. And it's going to be hard to acknowledge, once you've spent that money, that things may not work.

It's important to think information and not image. I think that there may be certain areas in the Internet and on-line services that do in fact, become a mass medium. But in financial services people aren't looking for entertainment; they're looking for information, and that should be where your focus is. To attract people to your site, to attract people to your services, you're going to have to deliver information.

And I think that what we're seeing a lot of the success in using the Internet is based on converting existing systems, simple existing systems, and converting them over to Internet technology, one step at a time. And as opposed to thinking about and trying to go out and gain new customers, it may be in many cases a better idea to focus on your existing customer base and what you offer them, and perhaps take some of those offerings and do them over the Internet in a better way.

To that end, I think First Albany Corporation has been a terrific example of that. Giles McNamee is the Senior Vice President with First Albany. First Albany is a highly respected investment banking and brokerage firm based in Boston. And they've done some very interesting things in terms of converting some of their research and information delivery systems to the Internet for their clients. Giles is a long-time Internet user. He's a Senior Vice President at First Albany, and his responsibilities include managing the institutional equity trading desk, and coordinating institutional equity sales and research. So here's Giles McNamee.

Giles McNamee: Do you mind if I close this?

Tim Duncan: No, that's fine.

Giles McNamee: The question is, will it work? Technology is such a wonderful thing.

I'm sure you're all aware of Microsoft's dramatic entrance into the on-line universe, Bill Gates' desire to further dominate our desktops. But we learned a little bit more about that at First Albany over the weekend. We upgraded our desktop operating systems over the weekend and when we arrived at work on Monday morning, we found the following message awaiting us: nothing. Yeah, we were surprised too. But the actual truth be told, you probably notice, I'm not smart enough to use DOS. I'm not smart enough to use Windows. I use a Macintosh. In fact, I've often been accused of being a Mac bigot.

Thank you. No, true story though. I'll tell you, last Thursday we affected an upgrade to our most critical proprietary Lotus Notes database, one which tracks our customer records, our customer contacts, and how we deliver research to our investor customers. And I was actually going out of town the day that the upgrade was going to happen, and I was talking to the VAR and I said, "You know, I need to take a copy of this with me on the road.

And the VAR said, "Well, how much space does the old copy take up on your drive?" And I said, "You know, 75 megabytes." This is a Notes app. There are no small Notes apps. And he said, "Well, the new one is 200 megabytes." So I'm thinking to myself, I don't have 200 megabytes of free space. A problem? No. An opportunity. I have a seven-month-old Powerbook 540c and I can toss it away and get a new PowerPC-driven 5300. I'm very excited about this. And so I'm reading through MacWeek to try to get a sense of what kind of different features I should order, so I think I'm going to wait a couple of months and see if they can sort the battery thing out and then come back and maybe buy one then.

Anyway, I'm not here to talk about Microsoft and Apple. I'm not here to talk about whether or not I need a new Powerbook. I'm here to talk about First Albany in cyberspace.

Just to give you a little background of who and what we are. First Albany is an investment firm which was founded in 1953. [We had] \$110 million in revenues at the end of our last fiscal year. We employ 650 people in thirty locations, and we are very aggressive users of technology. We've got an aggressive deployment of Lotus Notes, and if I showed you our VAR bills you'd be impressed at how foolish we were, that we should have talked to Tim Duncan first.

But you know, our data warehouse is now going through its second rev. We have an extensive internal Web. And so for those of you people who think that an internal Web is going to put Lotus Notes out of business, I would be glad to discuss this with you off-line. We run them both side by side. Then we try pretty much every new product we can get our hands on. We were an alpha and a beta site for AT&T's *Network Notes*, a product which may never get delivered, but we've actually been able to use quite effectively. We've been an alpha site for a product called *Wild Fire*, which is a follow-me roaming service that shows up at a lot of trade shows. It's pretty cool. We now currently are using Version 1.5. And we're beta testing, I think, four or five different software packages right now. And theoretically, as I signed the nondisclosures, I'm not supposed to tell you what they are.

Anyway, I am part of our institutional equity group. We are in the stocks business. We have sixty-five professionals in our group, located in five different cities; Boston, New York City, Stamford, Connecticut, scenic Albany in New York, as the name of our firm would imply, and lovely Burlingame, California.

Our primary focus is technology. My role at First Albany is that I'm responsible... I do three different things. I'm primarily responsible for a joint venture with Metagroup, which is a technology research and consulting firm located in Stamford, Connecticut. And with Meta we deliver user-oriented demand site information to sophisticated technology investors. Wall Street tends to look at companies and talk to the company management. We try to find out

what the people who are writing the checks are doing, which is sort of backwards. But we're from upstate New York, so that follows. I'm also responsible for all the interaction with technology investors, which is the fun part of the job. And the sweet part is that I'm responsible for our technical, internal technology deployment, so I get to get my hands dirty, and I get to learn about all kinds of new gadgets and toys.

You know, [given] the nature of our business, and having five locations, we are active practitioners of the virtual office. We use Lotus Notes, as I said, because it have a very robust feature set, and it's got an excellent remote access capability. Obviously, we use a lot of laptops. We have a very advanced telecommunication systems internally, so that all of our offices appear to be linked up with each other on open microphone lines all the time. We use, as I said, *Wild Fire*, which allows people to be, have one telephone number and have that phone number follow them everywhere they go. And I took my pager off so that it wouldn't go off while I was standing here and embarrass me. But we obviously have to use pagers and cell phones all the time.

We are in the information business. And what that means is we do research. There are a couple kinds of research. We do traditional investment research, which is, you know, "Buy this stock. We think it's going to go up." And as I said, we're in a joint venture with Meta to talk, which is a process where we talk about technologies and trends, and what people are really doing. You know, people who are writing the checks. Institutional investors pay us for providing them with value-added insight. If we know what we're talking about, we do thorough work, we will get paid.

And so our goal is to understand industries and the companies, do thorough research, and that also in turn will lead to investment banking opportunities for us. At least, our finance people hope.

But we, as I'm sure you all know, are in a very highly competitive business. We have lots of competitors. They're all bigger than we are. They all went to Harvard so they're smarter than we are. And you know, there's an awful lot of information available to institutional investors.

You know, they have access to the most sophisticated systems, and we have to compete with that. So to compete we need to provide quality. We need to be accurate. We need to be [able to] provide the information in a very timely manner. We need to be providing information of a different nature than our competitors so that it stands out. It's something different than the twenty-six other reports about Netscape that they've already seen. And we want, and we need to deliver this in a very user-friendly manner so that they like getting it so that it's not another problem.

So what makes us different? I think the most important thing is that we're users of technology, and we encourage all of the people in our group to personally interact with all the stuff they do and use the systems. Because if you use the stuff, you get to know it a lot better.

As you know, if you look at the price of some Internet-related securities, it's quite clear that none of the people who own those stocks has ever actually been on-line. When you get the little message that says, "No DNS entry," and they drop the line on you, maybe you wouldn't pay so much, you wouldn't pay two thousand times their earnings — if they had any. But like I said, I didn't go to Harvard so I'm not smart enough. No, seriously, Wall Street talks a lot of about technology, but the incompatibilities of the real world often escape people, and if you're not trying to actually plug them in yourself you sometimes don't know that they don't work together.

As I said, also what makes us different is that we try to focus beyond the technologies and the products that are succeeding, that people are actually buying, that are actually in corporate budgets, which is different than the normal spin. And as a consequence, we do an

awful lot of work on private companies, because certainly in software, and especially in the Internet, a lot of the people who are doing really exciting things are small private companies.

So that brings us to the on-line world. So what do we actually use the Internet for? Wall Street has always employed a lot of technology. As Tim mentioned, it's an information intensive business. People have quote systems. They get all kinds of news. There are transactional services available. You can even do on-line trades, on a closed system called InstaNet. The New York Stock Exchange has all kinds of links as well. There are order indication systems like [Autex] and Bridge. There's obviously also much publicized computer-based trading. These are all closed systems. They're all very proprietary. They all require specific LAN lines, point-to-point.

We see the Internet as an opportunity to improve, improve the ways we communicate with our customers. To us, the Internet's all about communication. We're in the information business, so communication is what we do for a living.

The Web particularly offers tremendous opportunities we think, to present very much in-depth information in a graphically friendly manner, not the sort of ASCII 10-point Geneva that's normally sort of — it used to swing around the Internet, but actually having it show up the way, more or less the way you want it to look. You know, I don't know if you... I'm sure you've all surfed around a lot and you see corporate Home Pages, and a lot of people's corporate home sites are sort of one-time-only visit situations where you look and see a little information on the company, isn't that nice. You know, we think that there is a lot more to be done, especially being in an information business. We think we can deliver the work that we're already doing in a very usable, user-friendly manner to our existing clients, and that people would have an opportunity to work with it.

And my screen-saver went off.

So the four basic things we do on the Internet: We communicate, we trade, we gather information, and we disseminate information.

First, communication. Very simply, that's what the Internet's historically always been about. It's a message system, point-to-point. Our investors' most precious asset is time. They have plenty of money — that is what they have. Time is what they don't have. And they have lots of people just like me trying to command their attention. They get inundated with mail and faxes. They get boxes and boxes of mail every day. And you can call them on their voicemail, and it's a one-way street. We find that e-mail actually works [for] talking to them. It crosses time zones. I personally interact regularly with investors in both the United Kingdom and in California, and if you're not in the right, if you don't call them at the right minute of the day, you might miss them, but e-mail always gets them, they respond to it. It can be stored and retrieved. You can actually say what you meant to say, as opposed to garbling what you meant to say when the voicemail message cut you off halfway through. And as I said, we always get a reply.

We have been trading on the Internet for quite a few years. There's an organization in Boston called Batterymarch Financial, which has been a computerized investment firm for fifteen years, I think. They've been trading on the Internet for more than ten years with brokers. When we first started trading with Batterymarch, they had a Telnet system on the Internet which you communicated with them at 300 baud. Happily, they're much more state-of-the-art now so you can actually deliver the packets and stuff relatively quickly.

Also, a lot of the closed-end systems that used to exist, like Autex and Bridge for indicating interest in buying or selling on a stock, have moved into open systems on the Internet — or open in a relative sense, obviously with a certain amount of security as well.

Fidelity has been a pioneer in this. They pioneered a system called FIX, F-I-X, Financial Information Exchange, which allows brokerage firms to send indications of buy or sell interest

directly to trade, from a specific trader to another specific trader, point-to-point. You know, I want to buy 100,000 shares of Apple, and literally you can point-to-point, you can send that directly to an individual or to a group. It's pretty cool.

And lastly, we trade by the old messaging system like e-mail on pages. I know that sort of sounds silly, but investors tend to spend a lot of time not at their desks. They travel a lot. They go to a lot of trade shows. They go to a lot of conferences just like this. You know, they go out and see their companies. They kick their tires. How do you get them? Well, you can send them e-mail because that will find them anywhere. It doesn't matter what hotel room they're in or wherever, they'll respond to that. Or we have a Skytel pager, an Internet pager gateway, and we can send e-mail directly to people's pagers, which I personally did at a trade last week. I hit them on their pager, and the person was at a conference someplace in Arizona, called back, and bought. So it does work.

We use the Internet for information gathering. It's a tremendous resource for this. Our corporate finance guys use Edgar and the other federal repositories for getting company information and demographic information and the like. Research analysts use the Internet to do company research and product research. They regularly visit company Web sites. They look at the product forums to see what people are saying about the companies and stuff, and what they're saying about the products. We get user feedback.

It's one thing to go to a company's Web site and see their most recent press release on a product, but it's another thing to go into an AOL or a CompuServe forum and find out what real-world problems the user is having trying to install the same product that was so much heralded in the press announcement. And that's the real world. That you can find the stuff out there, it's out there, it's great.

And lastly, we do find all kinds of great presentation materials. Some of the things that I used earlier and this little item which I found the other day are all available on the Internet.

But the most important thing, because we're in the information business, is disseminating information. As I said, we use *Notes* and *AT&T Network Notes*. We have dial-in access for investors into *Notes*. We like this because the applications are very robust and they can search and sort them and play with them in lots of different ways. They deliver PDF files and have for quite a while, and it works pretty well. So you can not only look at things but you can also download them and take out different bits and so on. That alone has saved us a great deal of money and probably more money than we've spent on all of our Internet products and projects put together.

We used to do a lot of printing, both for internal and external use, and we had an entire printing operation, printing presses and all kinds of little guys that did printing. And that's all gone away, because it happens electronically. We've saved on the mailing costs. It's been tremendous. We also find that e-mail complements fax and paper mail. You can send stuff to people, and investors get stacks and stacks of mail. But if you send them e-mail, the same research report, they'll actually see it and read it, and they'll respond, they'll send you a little message back.

And lastly — and I think most importantly, because this is where we spend a lot of time and energy — is the WorldWide Web. We think this is where the biggest single opportunity lies with us, because this gives us the best point-to-point opportunity. You know, a lot of people don't have *Notes* on the desktop just because an opportunity to pretty much access every single one of our customers.

And to [inaudible], we built a couple of Web sites, and [I'll] talk to you first about the background of how we went about it. First, the corporate Web site, which is more general.

The goals of this were to provide information about the firm, who we are, who our people are, what they do, some stuff out of our annual report. First Albany is a public company,

so stock is publicly traded on NASDAQ, so there's some information about that kind of stuff. There's samples of our various kinds of products, and the firm as a whole has municipal bond deals that we might be working on, financial services products and the like. And it was very important that we have some interactive feature to it so that people could respond, and there's different ways that they can send us messages and say they're interested in things, and that provides leads for our retail salesmen to follow up on.

This is pretty much a standard corporate Web site, without really significantly robust goals. However, in our group we tried something a little more aggressive. We looked at some of the Web sites built by our competitors. The graphics on Morgan Stanley's Web site are tremendous, but it's pretty much their annual report. And [Volpe-Welty] also has a beautiful Web site, but I don't think they've updated it in a couple of months. It's difficult in maintaining a Web site. So we had a few goals that we wanted to affect when we built this thing.

We want to be able to provide controlled access to all of our published materials, both in text form so they could see it on the screen and play with it, and also so they could download it in its original form with all the fonts and all of the graphics and the tables and the graphs and charts, and all of that kind of good stuff.

It had to be user-friendly. I mean it had to be a no-brainer, a couple of points, not ten, not a lot of steps involved.

The information had to be up-to-date, and it had to be regularly refreshed. We needed to have full-text search capability so that people could go in — and the volume of stuff we put together is a lot — and know what to look for, and if you've got full-text search you can find whatever it is. At least that helps a little bit.

We needed it to be secure. I mean, obviously security is a huge issue these days. It will always be an issue. You know, certainly our chief financial officer, our trading desks are a little bit concerned, anytime anybody is dialing into our firm, that these people may have access to what we're doing. So [there are] a lot of issues about firewalls.

And lastly, I thought the most important thing was that this should not be MIS intensive. We wanted to build something that was fire and forget — just set it up and it was going to work, and you weren't going to have to do anything to it more or less after the fact. And that is a real challenge if you want it to also be up-to-date.

So what were our solutions? We used a product from Lotus called *Internotes*, which translates our *Notes* databases into HTML. This allows for regular replication, so all the stuff that's live that we're using within our virtual office is live on the Web.

This also allows for the transport of PDF files. This has been a slight issue with our firewall, and I'll get to that in a second. Some days it works better than others, but it will over time provide all of the robust features, or most of them, that are currently available from AT&T *Network Notes*.

You know, we had to build a very elaborate series of firewalls, both software and hardware, to protect what was inside the firm from outside, and it seems to be working. I'm sure that's not a challenge. I don't want anybody to try to break in. If you do however, I would appreciate you just dropping me a line and letting me know so that we can fix it. We use *Netscape*, a *Netscape* server. It allows double password protection, and that's got an additional benefit in that we can see who's using the system. We can see what they care about. We can see, after we've seen who's been in, we can see what the hits are and what they're looking at, so we can do follow-up and we can do additional work with them if necessary.

There were, of course, some problems. There are still some problems. The most important thing to remember about the Internet is that everything available for the Internet is enormously immature. It may be a great idea, great software, but it doesn't always work so well.

We experienced a lot of competition for MIS resources, and I think everybody is going to have that problem. In the client/server world you just don't have enough bodies to do all the MIS work you need to do.

The security firewall issues have been a big deal — getting the packets outside the firewall of information in the replication cycle, but keeping the replication process intact and letting people in, is a real issue.

We've had a lot of operating system conflicts and software conflicts. *Internotes* runs on NT. Our internal *Notes* servers run on OS/2. We run UNIX, Mac and PC internally. And there are a lot of these things. I mean, the biggest deal, the biggest thing is that it's all easy to use, it's all easy to set up, but it doesn't always work well together; and it doesn't matter what they tell you downstairs — or excuse me, across the hall — it's not always quite as easy as it sounds. Sure it takes two hours to install each different product; it's the three weeks to get them to work together which is sometimes more complicated.

Also, what turned out to be much more difficult than we originally envisioned [was] the full-text search thing, [which] is not quite as simple. We are still working on that problem, that part of the process. Actually I hope to have that fixed either today or tomorrow.

So what are the results? We have two Web sites. Feel free to take a look. The first one is the corporate Web site. The second one you can't get into, unless you get a password — unless, of course, you are good at that kind of stuff in which case, as I said earlier, please send me an e-mail and let me know how you did it.

So what did we learn? We learned a bunch of things. It would have been faster and cheaper to outsource. Much cheaper. And it would have taken a tenth of the time. But if you outsource it you don't have the fun experience of being able to learn how to do this, and then I get to tell you what a great, great time we had doing this. So that's worthwhile.

You know, the security issue is complicated and it will get increasingly complicated. Everybody's client/server world looks different than everybody else's. Everybody's network is different. The issues are always more complicated than the vendors will tell you. And it is both a hardware and a software solution, and I would suggest that you don't let anybody try to tell you otherwise. As I said before, Internet software is tremendously immature. You know, the stuff's all in its first rev, or its second rev, and there a lot of problems. There are a lot of bugs. Things go down for no reason, but that's life on the Web. And as I said before, the products are easy to install; it's making them work together which is really complicated.

But I'll tell you, the thing that stands out about all of this is I have absolutely no idea why Netscape is worth three-and-a-half billion dollars. I mean, IBM paid three-and-a-half billion dollars for Lotus. I don't know if that was a good buy either. I have absolutely no idea. But I do know that the future is very important. And we are really excited about being on the Internet. We're an information-based business. We are a natural for the Net. This is what our business is all about. You know, every time we find a new way to communicate with our clients it gives us a new opportunity to do business, and we're going to take advantage of every opportunity that there is out there. The Internet, compared to all the other things we do, is cheap — and it's an easy way to get point-to-point, directly to people we know who care about stuff we're doing, our existing clients. And all I can say is we're really excited about the future. This is going to be a really big year for us.

Anyway, thank you very much.

Tim Duncan: Open Market is based, along with I think eighty other Internet-oriented companies, in Cambridge, Massachusetts. And in my opinion it is really one of the truly exciting companies out there doing things with regard to the Internet. And not only that, I think they've managed to distinguish themselves tremendously by being about the only company out there in

the United States that's doing Internet-related businesses that's making money, and hasn't gone public yet. They are highly focused. They've combined a brain trust of very intelligent MIT [people] and folks from other places with a technology background with people that have a business understanding of specific vertical markets such as publishing and finance. They're delivering products, software products and solution products to those specific industries, and I think are going to be really one of the top stories that come out of all of this in a year or two. I mean they are already.

John Guerster is going to present today with Dick Moorman. Dick is with Banc One. He's responsible for the sale of electronic commerce and interactive EDI programs for Banc One. And John is responsible for financial services. He's the Director of Financial Services at Open Market. And they're going to focus on the solutions they're providing for Banc One in terms of business-to-business products.

John Guerster: Good morning. Can you hear me back there? Just a thought following on the last presentation. I was talking to a friend who worked at Cal, and who's a young, eager salesperson, and he was talking to some institutional clients and they were picking on him pretty hard because they wanted an earnings story for all the issues he was trying to sell to them. And I was actually at a pub in London with him about a month ago. And he said, "This Internet thing is really ticking me off." And I said, "Why?" And he said, "You know, all this time I learned about earnings and I go back to these guys and push earnings, and this IPO from this company called Netscape comes out and I call up my investor and he's totally angry with me because I haven't called him. I said, 'But you wanted to talk earnings.' He goes, 'Yeah, but this is the Internet.'"

And I appreciate some commentaries on this segment and how exciting it is, but it is true that it's an emerging industry, and one of the things that Dick and I would highlight is that there are some things that are being done right now, today. And one of the things we learned at Open Market is that there is no textbook, so much of what we think we're getting is learning. And that's going to drive what's going to happen over the coming months certainly. So with that, I will try to manipulate this system.

[Tape change]

John Guerster: Okay. What we thought we'd do is just go through a bit of background on Banc One and Open Market, then go into a little bit about how we view the market. Actually, this will be a little bit of Open Market's perspective on what we're learning from financial services institutions about what they think when they look at the Web and the Internet and how it can change their business model. Then we'll go into the business-to-business segment. There's been a lot of hype about the consumer to business segment; we thought we'd focus on the business to business segment. And then we'll go through a case study as to what we're doing with Banc One. We're going to sort of pass back and forth, but please feel free to jump in and ask questions if you think it's appropriate.

And lastly, we'll finish with some summary and observations.

A bit about Open Market and then I'll let Dick certainly talk about Banc One. We are here in Cambridge, and we've been growing very quickly. For those of you who saw the article in the *Boston Globe* this weekend, much of it was true, actually. One of the challenges in the PR space in the Internet and the Web is that very rarely is the article totally catching what's going on. And we joke about it. And so when we see an article that's true, we're a bit surprised. But in general, it suggested that we're growing very quickly. We're now at a 180 people.

We actually have a development site now on the West Coast, and we have some great folks from Xerox PARC we've hired. They're doing some R&D for us, as well as some development engineers. And Greylock Venture Capital here in Boston was one of the venture capital firms in on our organization, beginning of last year. And since then, we brought in financing from Time Tribune and Adventist Publications.

Dick.

Dick Moorman: It's always interesting when you try to describe the positioning of commercial banks today in the marketplace. What I can tell you is that Banc One has approximately \$90 billion in assets as of the end of the third quarter. I haven't checked this morning's headlines, so I think we're still one of the top ten banks in North America, but we never know for sure. It's a moving target.

In terms of capital measure, which we are very proud of — we are one of the forty largest banks in the world in that regard. We are a well capitalized financial institution. We operate in thirteen states with banking charters. We have other non-bank subsidiaries that practically take us throughout the U.S. and other parts of the world, and we have roughly 45,000 employees looking very closely at things that Jonathan and I are talking about.

John Guerster: I thought it was worthwhile just to give you a picture of the segment as we view it. Again, one of the challenges in the public positioning of what's going on in Internet and Web is to understand what each company is doing, because very often there's a three-person firm suggesting that they're doing everything on the Web, and it always catches us a bit by surprise. And then there are these large organizations who put together partnerships. And much of the challenge right now is understanding what specifically will be delivered from these organizations and trying to plan it into your future. That's a bit of what we spend our time on.

I guess I'll use one of the terms we used very early on with our company, which is that we tend to think of ourselves like plumbers. If you can think of the Internet as a big open network without an infrastructure, what we're trying to do is essentially put the plumbing underneath. And the way we look at it is from a segmentation point of view, that there's been some publicity around, companies like UUNet for instance, going public, raising capital to build an infrastructure to allow people to get access to the Internet. And certainly our friends from Netscape and Spyglass are in the space of making Web browsers and Web servers, and they raise capital in order to push their model forward aggressively in the next several years.

We tend to operate from the Web server and go back. And essentially that's the focus of our company, this quote-unquote plumbing model if you will. And there's a bunch of issues in there. In fact, one of the biggest certainly is security, and that's worthy of an entire day-long discussion.

I will mention to you one thing. Actually, yesterday I present in San Francisco at another conference on electronic commerce, with a guy named [Guidas Barducas] from Microsoft, the STT Product Manager. We were both presenting and we were commenting before the session that we've been giving the same presentation on security for quite some time, but they had presented us from VISA, from MasterCard, from Microsoft — certainly Open Market was included — and what we found was that we're getting to the point where everyone is saying the same thing. And that's an important message, because security is a large topic. What it suggests is that there's some market dynamics happening here where people are looking at the same issues — and we can go through those off-line — but in general it was interesting that it's taken about six to nine months, six to nine Web months, as we call them, for the market to get up to speed on the general principles and what's necessary in the area of security.

On the left is a bit of a view on how we think most financial services firms have traditionally looked at this sort of model. It's a new segment, and most people come to us with the idea, at first, that it's a transaction model. It allows them somehow as a bank or a financial services firm to drive transactions, because that is the core business they're in. And certainly they think of it as a mass market or a delivery channel model. One of the things they're less clear about is whether it's a content or a services game, and I'll go into that a bit later on. In the publishing space, many publishers who have content that's interesting are thinking about providing transactions at the back-end so they could be in two segments.

On the right, is actually Open Market's view of what we think financial services firms — and probably most industries who are looking to segment — should think about, should focus on in any business model they'll explore for the Internet or the Web.

And the first one on the right is probably the most important, and that is relationships. I'll go through an example about what I think is happening there, just after I go through the rest of the points.

The ability to generate new, differentiated products is the opposite of a delivery channel, actually. Delivery channel suggests you have a product and you push it on the channel; what the Web and Internet should be focused on and be used for is developing a completely customized product.

And that speaks to the third point, which is that you arguably could look at a model where every customer has their personal on-line service, and this can be done for almost nothing or for very little incremental costs. That's a very different way of thinking about this.

And lastly is brand. I'll use the example of Time, Inc. How many of you have been on the *Pathfinder* service? Okay. *Pathfinder* actually is running on all of Open Market's infrastructure. One of the things they came to us very early on with is that they wanted to build this new service. Now, what's interesting if you think about Time is that it has incredible brand awareness. The brand awareness, however, is associated with *Time* magazine, *Money*, *Sports Illustrated*, those sorts of publications, the physical magazine you pick up at the airport before you jump on a plane. And what Time said was, "Listen. This is such a different paradigm. What we need to do is think about establishing an entirely new brand. And that brand should not be associate purely with the content game we've been in until now, because what we want to do is electronic commerce. We want to have a complete on-line service." And so they took a huge step.

For a consumer-oriented company like Time that was a major statement to make. You have to think through what the thought process was. But what they were saying was, "This is a new game, and *Pathfinder* is the name we're going to stick on this "thing." And I can tell you, having worked closely with them as an organization, we've learned a lot with them over the last several months. They get millions of hits a day. They have hundreds of thousands of users. And what they're doing is they're learning. But the important message to take away is that they chose to establish an entirely new brand for this paradigm, not leveraging what the word Time stood for already but establishing something new. And I think that will have significant value going forward.

Numbers. Let's see. I talk about Web months, and a Web month is when... About five times as many things happen in a Web month, so this is all of about five or six Web months ago.

People were pretty excited to get hard data on the Internet and the Web. I just grabbed this bit of data from a recent Alex Brown report that came out on the Web; and I speak less to the numbers, the revenues there, but more to the trend. And so what's happening now, if you saw even some of the press yesterday, is that CommerceNet and Nielsen came out with a report, the first credible report on Internet users. [There are] some demographics, some user

trends, and certainly a fair number of research firms are looking at establishing the back part of that.

One reason is to understand the consumers, and the other is to understand what businesses are doing. And both of those bits of data are now becoming available. I can't ascertain whether those are credible or not; what I can tell you is that a lot of those institutions are asking firms like ourselves to give them some hard data.

And I'll tell you, I'm doing my business plan for next year, and I have no idea how to forecast this thing. Don't take that back to my boss, but I have to give them some ideas because much of this market is built around resource planning. And you've got to be able to handle a certain opportunity.

Well, with that said, I'll actually hand-off to Dick to cover a bit of what we've learned in focusing on this segment for this latest opportunity.

Dick Moorman: What we have tried to do is identify in the business-to-business community where opportunities exist. A lot of the newspaper hype and all the publication hype has been more on the consumer-to-corporate side, and where are some of the fancy things going on electronically; as corporations begin to go through — and have gone through in the last several years — a whole re-engineering process, they're looking for ways to reduce and cut costs on the administrative side.

One way they have chosen is to obviously look at how they do corporate-to-corporate communication and contact. The typical way is through the standard EDI, electronic data interchange programs, which have been pretty much driven by various value and networks that are already in place. Fine. That's no problem, except that there is a cost-related issue there. What we're beginning to see are businesses looking for alternative ways to keep the electronic peace, explode into more than just typical business-to-business information, and get away from using proprietary networks and try to go to as much of an open network potential as possible.

Information capture, as Alex said earlier and others have said, is the key to a lot of what we're looking at here. It isn't even just from a banking perspective, it is not just funds movement — it's all the information related to it, which will become an integral part of all this.

And then, ultimately, customer service. I shouldn't say ultimately, but related to it will be customer service, and how in fact you can complete the window or the model of the entire electronic commerce process.

John Guerster: Go next?

Dick Moorman: Yeah.

John Guerster: I did it.

Dick Moorman: I think, as you look at the business-to-business aspects of electronic commerce, that it changes a little bit the perspectives that various parties bring to the table. In the traditional environment the bank will go in and talk to the corporate treasury department, work out what needs to be done and the business is completed, and the contract may be signed. When you start to elevate this to the level of electronics and get away from some of the financial aspects of it you begin to change the terms in which the various parties do business.

In Banc One's case, we've looked at where we have strengths and where we need to strategically partner with other organizations to bring together a package of services to the business community, and that works well whether you have an existing relationship or not. If an existing relationship already exists, what is necessary is to get beyond where the traditional

relationship resides. Typically that is in the treasury and in the finance area; and we have found, quite frankly, that over the last few years where we have scored successes in the whole EDI marketplace has been getting past the financial area. Incorporate them into the process, but get to the owners of the process. If it's a purchasing application, if it's something that affects payables or receivables, get to those folks if you can and spend some time talking about what makes their job difficult today and what can be done to improve that and change it.

John Guerster: Actually, if I could add something there... In a prior life I worked for Hewlett-Packard in the hardware space, and one of the challenges for any of the sales reps in the field trying to get to a model of actually being able to sell their hardware was to get to the decision-maker. Typically, it was some sort of person in the IT space. My first day at Open Market there was a CEO in a back room, one that had no air conditioning, and he was there with a whiteboard sketching out what his business model was going to be.

And what it speaks to — and certainly the things we've learned — is that the people who are looking at this are the business side of the institution. And it's a very interesting model. Actually, the comments that were made earlier spoke to it, the fact is that business people are making decisions on this space. It is new, and so to the extent you can get to the business folks, they're going to understand the metrics and the way that they can expand the business model and drive that as a process in the organization.

Dick Moorman: It's typically a group decision, but generally speaking we have found that if you can get to the owners of the process then they drive the process upwards, back up to the ultimate decision-makers, and it makes for a much smoother process.

But when you talk about organizational challenge, the real key is that oftentimes the people you are talking to are going to be directly affected by the change that occurs. And it takes an awful lot of hard work in getting folks to work together in unity to figure out what the best bet is going to be here. There will be some changes, obviously. If through this process we can eliminate a lot of the administrative paperwork behind the purchasing application, or the processing of an accounts receivable application, the focus then is how resources can be productively employed, because they won't need to be productively employed in that particular process. So it provides for some interesting discussions as you get deeper into it.

And I guess, as far as the significant drivers of business transactions, I'd say it's almost more the amount and type of information that really tends to get the focus. Cost is certainly a factor, but quantity, large quantities of transactions will often drive the process and the decision-making process to change to another process.

That's kind of a general overview. Jonathan, did you have anything more to add to that?

John Guerster: No.

Dick Moorman: That's kind of a general overview. Looking at the next slide we have up, we thought we would walk you through a little bit of a specific business application that is currently up. It uses the Internet and involves large groups of buyers and large groups of sellers with a common need.

We spent some time over the last nine to twelve months working with a company called [Rowe Communications], which is also located here in the Boston area. That company basically is in the business of providing subscription agency services to link technical, scientific and medical research libraries to the publication industry that provides the serials and periodicals on an annual or more frequent basis.

That whole industry has very typically been labor-intensive, very much paper-driven in the past. A major library can order thousands of periodicals on an annual basis. It was all done through issuing paper purchase orders to the subscription agents, who then would take and consolidate those and send massive quantities of paper to publishers, along with a check or two checks representing the full amount of the payment. It was a long purchasing cycle. The order could be entered today, and it might be six to nine months before the actual publication appears, because the ordering occurs one time a year. Delivery occurs throughout the year. The third party in the process was taking a cut of the business, and therefore everybody was participating. The backlog, I think, was a major part of this, in that we had the long lead times and it was very difficult in the case of customer inquiries and customer service in the traditional marketplace to know where things stood.

What we were able to do, working with Rowe and with Open Market, is partner together into a program that allowed for the delivery of information at the library side, the electronic catalog of all the major publications available produced by the major publishers worldwide — available on PC and on software — that the library could then go through and in one move electronically enter purchase orders for all of their publications for the next year.

We'll go through the flow in just a second. The actual movement would occur electronically. Most libraries and most publishers are already communicating on the Internet, so there was already a comfort level of how do we use this animal here we call the Internet. This allowed the link-up to occur and ultimately, in addition to the link-up, we were able to move all of the funds electronically from the library's accounts through a system into the publisher's accounts.

And ultimately we see this becoming a worldwide program right now. Most of what we're doing is domestic; the next step is to incorporate full electronic capabilities in the payment side worldwide.

As you look at that next slide, you can basically see the parties are fairly few here, and the movement of funds occurs, as I just described, along with the communication, between the libraries and publishers. And it gives access, where before it was not available, for publishers and libraries to communicate directly with others and with each other. So it really opened up the communication links completely.

What we found to be valuable about this from a financial servicing standpoint is that it allowed us as a bank to get closer to two marketplaces that we've always felt would be good markets to explore. And that's the university library market, if you will, as well as the publishing industry. This provides that kind of an opportunity. It allows both sides of the equation, both the buyers and the sellers, to dramatically improve their own internal operations, and we've heard some ballpark numbers now that are fairly substantial in terms of cost savings from the standpoint of the library's side.

John Guerster: There's some interesting market dynamics going on here as well, because it just so happens that libraries happen to be typically connected to the Internet, and publishers are pretty interested in the Internet and the Web because they see it as a distribution vehicle. In this case, the way we've architected the solution, they're capturing their order information through the Internet as well.

Dick Moorman: Right.

John Guerster: But those are some good models of some trends that are happening that make this model very successful in the short term.

Dick Moorman: We have been in a test mode for a few months, and we're actually moving into a live mode right now. And we're very pleased with the results. But you can see here the implications of this particular application; we found a way to deliver a traditional product at a much lower cost, substantially lower than previously. It's instantaneous information and movement of funds. The business model, really, is interesting. We not only have authentication, we have reporting and the movement of financial transactions. Everything is done electronically.

Jonathan can speak a little bit more to security in this area. What we see really is a model that allows us to determine where there are other markets like this, with large quantities of buyers and large quantities of sellers with this common need throughout, as a model to bring to the table.

John Guerster: One of the wonderful things about the Web is that it lets you do anything. And one of the terrible things about the Web is that it lets you do anything.

Dick Moorman: Right.

John Guerster: So the challenge in this sort of model is defining what exactly you want to do. And certainly the way that Open Market looks at it is that fundamentally there are three things going on in any business process: there's authentication of the individual using this environment; there's reporting, integrated reporting going to the bank or to the customer or to the merchant who's selling the product; and then there's the financial component at the back-end, be it a credit card, or be it an ACH in this instance.

And if you look at those three things, and address those three things, you have addressed any fundamental business problem. The challenge is to define what exactly are you trying to do on the front end. In this case, it's libraries and publishers; but as you can expect there are plenty of situations where there is this intermediary, and there's a process of disintermediation going on, and looking at should this intermediary continue to play a role between two parties.

Okay. In summarizing it, actually, I will just speak to a second and third point; I think the first point will be discussed out there on the trade show floor. The Internet should sell itself to most people.

But there's two things going on in the second point. One of the challenges right now for people looking at projects in the space of the Internet and the Web is to justify it on an overall basis, not on an R&D basis. A business-to-business sort of model allows you to do that, because you have transactions to the back-end, and you can build a business case much more effectively than you can trying to judge the effectiveness of an advertising model using a Web site, for instance, from a consumer point of view.

And the second thing I would emphasize is that in this market there's a substantial premium for early entry. And what that speaks to is the fact that if you look at someone like Time, for instance, to the extent that *Pathfinder* delivers you a valuable service and continues to upgrade it and add more value, the odds are you won't switch to another service that comes up and it competes against it. They've gotten out there early and they're locked you in as a customer, and that's very true for all the different segments we're looking at in each case. To the extent you can lock in an early relationship with someone, you stand the benefit of being able to continue to drive that relationship going forward.

Thank you very much for your attention.

Tim Duncan: I estimate that we have 320 people in the room and we have coffee service for 8 people outside. We're running a little bit behind time, and what I'd like to do — we're never going to get everybody out and everybody back in.

Mary Ruth from Fidelity is going to talk. If we could take just maybe five minutes, and if we could just stretch where we are, a couple of people have to leave the room. That's fine. And we'll pick it back up in five minutes. We'll have the Fidelity presentation and then we'll have questions.

[Break]

Tim Duncan: Let me introduce you.

Mary Ruth Moran: Okay.

Tim Duncan: Okay. I think we're going to get going. If you could take your seats, please.

Mary Ruth Moran: Yeah, I think we're all set.

Tim Duncan: There's been a lot of hoopla about Microsoft that we've all heard over the last five years. But I think that right up there with Microsoft in terms of corporate success stories in the last decade — you would have to rank Fidelity right up there. Certainly in the financial services industry, there's been no greater success story than Fidelity. They're the largest mutual fund in the country. And I think most importantly, I heard Steve Case say a month or so back when somebody was delving into all sorts of technology issues, he said, "Look. This isn't about technology. It's not about technology at all. It's about getting people what they want."

Tim Duncan: And I think that's something to remember, particularly in the financial services industry. I think that's something that Fidelity has really taken to heart over the last years, ten years, in getting to where it is today. They've used technology very effectively, but you wouldn't know it because their focus is basically on getting people what they want, and that's why they've been so successful. I think this is also true in their accomplishments on the Internet so far. I think anybody that's seen their site on the Internet and what they've done is going to be very impressed.

Mary Ruth Moran is the Senior Vice President at Fidelity. She's responsible for the company's WorldWide Web and Internet strategy, and also responsible for the electronic distribution channel as a whole. She's a graduate of Wellesley College and Harvard Business School, and she's going to talk today about what Fidelity's done so far, their successes and what they've learned.

Mary Ruth Moran: Thanks. Good morning, and Happy Halloween to all of you.

Has anyone here in the room ever been to the Ed Sullivan Theater to see the David Letterman show? Yes, so this room is about as cold as Dave keeps his studio. But we'll try to keep everybody awake and get you out of here on time.

As Tim mentioned, I'm from Fidelity Investments. And the comparison to Microsoft is flattering, I think. I want to tell you a little bit, give you a little bit of a behind-the-scenes look at our experience with the WorldWide Web thus far. As some of you may know — and I see some familiar faces in the crowd — Fidelity has had a site on the Web for about nine months now. And given how many people were there then versus how many people are here now, I guess in some respects that gives us veteran status. And I hope from sharing some of our

experiences with you today that we can give you a sense, those of you who haven't put a site up, on what to expect, what in general terms the investment in time and people looks like to put a Web site up and to keep it operational.

To that end I'm going to address three things this morning. The first one is what it took internally for us to get established on the Internet. I'll tell you a little bit about how we're doing, and give you a sense for where we're headed over the next year or so.

I think Tim did a great job in introducing this whole discussion this morning. He gave us several points, several observations that he and his firm have made about marketing or distributing products and services on the Net, that I would say is probably the first place that I've seen any conventional wisdom grouped. And clearly the conventional wisdom is still emerging about how best to use the Internet to serve your customers. Throughout my remarks this morning there'll be some recurring themes that basically revolve around the importance of really rethinking the traditional ways that you do business and adapting to what we believe is a fundamentally different way of doing business.

There are sort of three truisms that we've found. One is that what you don't want to do is do business as usual. You want to maximize the flexibility of the medium of the Internet itself to deliver unique content to your customers. You want to add some value for them having taken the time to visit your electronic storefront, and you want to give them a reason to come back again and again. So if you'd keep that in mind as we walk through some of my slides this morning, you'll see that comes up again and again as sort of the rules of the road, as far as we're concerned.

Let me give you a little bit of background about Fidelity for those of you who don't know us. We are a large financial services firm in the country, servicing about 20 million customer accounts. Those accounts are mutual fund accounts, discount brokerage accounts. Many of you may be participants in 401k or 403b plans that are administered by Fidelity. All told, those accounts gross up to about \$350 billion in assets under management, making us worldwide the largest privately-held financial firm. And in fact, we are a worldwide operation, which clearly has implications on the Net. We operate not only here in North America, both in the U.S. and Canada, — a united Canada, I hope all of you saw this morning — and in Europe, and in Asia.

We have three traditional ways of distributing our products and services: by telephone, mail, and with bricks and mortar. Our telephone business is extensive. Throughout the country, we have located five telephone centers, and we handle upwards of 400,000 calls a day from investors. We are one of the U.S. Postal Service's largest clients, as you can well imagine. And we have built for ourselves in the middle of the country just massive in-house direct mail capabilities. We send out something on the order of 100 million customer statements a year, and you can imagine all the other paperwork that investment transactions generate. And we have eighty investor centers located throughout the U.S., our equivalent of the bank branch.

So you can see that we're fairly ubiquitous in the traditional channels. And it's our intent to be equally ubiquitous in what we view as a fourth distribution channel, and that is the electronic distribution channel.

Our Web site, introduced last February, was really one in a series of forays into the electronic marketplace. We had owned and operated our own proprietary trading service, which goes under the name of Fidelity On-line Express, for several years. And we've had, what we call, an on-line investor center on Prodigy since 1992. Since we launched our Web site, we've also launched on-line investor centers on America Online and Microsoft Network.

[Tape change]

Mary Ruth Moran: To reach our customers and other investors electronically made a lot of sense to us, so we made the decision to form a specific group called Electronic Marketing, which is dedicated to attaining this ubiquity in the electronic channel. And we have a very simple mission, and that is to establish what we think of as the fourth distribution channel.

There is definitely, in our mind, a distribution paradigm here. Reaching people electronically in many respects is the equivalent to reaching them through the other three traditional channels that I mentioned.

On the other hand, to Jonathan's remarks, what you reach them with has to be a distinct product. And back to my sort of guiding principles earlier about value-added content and reasons for people to come back again — you do have to develop a distinct product to put through this fourth distribution channel. In fact, at Fidelity we regard it as a distribution channel. We clearly are in, as all of the panelists have indicated this morning, an information intensive industry. And another part of our mission is to combine the power of digital technologies with what we see as unique content assets available only at Fidelity to deliver content that's interesting, that's entertaining, and that's relevant to the investment decision.

One of our other panelists talked about the importance of having objectives before you begin experimenting in cyberspace. In fact, we had three very simple objectives when we began. We wanted to satisfy customers. We wanted to do it efficiently. And we wanted to simplify the investment decision-making process for people.

We found that about two-thirds of our customers owned PCs, and this was about a year ago when we did this research. Half of that group was already on-line. And these numbers are, by the way, BC numbers, these are "Before Christmas" of 1994. So we knew that there was a market out there that wanted to be reached electronically. In fact, we went a little bit further and we asked our customers whether or not they were doing any financial business or any personal financial management using their PCs. And half of them said they already were. Whether that was some spreadsheets that they had jury-rigged, whether it was one of the personal financial software packages, they were beginning to be immersed.

We also knew that this could be, if we managed it right, sort of a classic win-win situation. Delivering products and services and service on-line could be very efficient for us obviously. But also it could be very efficient for consumers.

One of our panelists mentioned that the most precious commodity that investors have is time. That's clearly the case. And we'll talk a little bit more about this later, but we've found that we can cut down what is for them typically a ten-day to two-week process to minutes.

And finally, to some of the points I made earlier, we clearly wanted to deliver actionable information. We wanted, when people finished a visit to our Web site or any of our other electronic storefronts, for them to be able to walk away having made an investment decision.

So we were pretty comfortable that we had sort of laid down the foundation for a successful experience on the Internet.

What I want to do now is tell you a little bit about what we had to do internally to make this work. And really the first thing is that anything that you thought was true in the traditional channels, any conventional accepted ways of doing business — we didn't throw them out, but what we did was we put them aside and we started with a blank sheet of paper. We really needed to rethink how we did business from the ground floor up. We needed to look at content in a new way. We were no longer going to be constrained once we went on the Web by the size of the ad that we bought in the *Wall Street Journal*, or the number of pages that we could put in a brochure. And we had to think long and hard about the resources it would take, to be able not only to get the site up and running but also — in the parlance of the accountants — to run it as a going concern once it was up. And we've had the experience, that I think Tim

talked about earlier, where it is X dollars to get the site up and running, and we would say that 4X to keep it up and running is probably even on the conservative side.

In terms of rethinking how we do business from the ground floor up, I think Fidelity is unique, probably one of few companies its size that is continually in a process of reinvention, to take advantage of new opportunities.

And so, for example, we have several thousand representatives staffing our eighty investor centers and our telephone sites. And we've done a pretty good job of training them to respond to investor inquiries and to help investors plan what to do with their money, either face-to-face or in person. Now, we needed to think about how we would have them work with investors electronically, like through e-mail, as Giles mentioned earlier.

We had just spent a lot of time and money building one of the largest facilities in the country to process paper. That was fine and paper will always be with us, but we had to plan for the advent of a time when we would be delivering a lot of the information that we deliver by paper today in something that approaches a paperless environment. And for those of you who are in my business, you know that it is one of the most highly-regulated businesses in the U.S.; we had to really work with the securities regulators so that we could help ensure that the combination of the regulations that are designed to protect investors and the technology worked hand-in-glove, as opposed to at odds with one another.

This was on one of my earlier slides, and I saved it until now. What we really had to do was make a conscious effort to resist what — the term we coined was “brochureware.” We had to really resist the impulse to take all of our existing collateral and simply convert it to HTML. Nobody would care. What we really had to do was take a good hard look at all of those assets that we had internally, the ones that the sort of immediacy of the Web and other on-line channels would allow us to deliver and that we'd never been able to deliver through traditional channels. And we had to rethink the nature of the material that we were delivering.

We had to make it fun. We run contents on our Web sites to encourage repeat visits. We had to make it interactive. We have a lot of planning worksheets that people can fill out on-line to help them get personalized or near-personalized solutions to their financial problems. And as I said earlier, we had to make it actionable. They had to be able to do something, to take some step once they had completed their visit. And I probably don't have to tell you — any of you who are operating Web sites right now know the lure at this point — it is important to keep that content fresh and current. That clearly has resource implications.

We've got systems resources that we need to have operational every day to maintain this Web site. And we know that we need time as a resource, because it doesn't take a lot of time to convert a brochure to HTML, it takes a lot of time to develop truly interactive content that's appropriate for the electronic channel.

You need people to maintain that content. And all of that costs money. I would venture a guess that somebody in the question-and-answer section would probably ask me, “How much money?” And so I thought we would anticipate that. I'm not going to tell you exactly how much money we've spent, but I am going to say that it is important to start now, however small you must start. Just understand that for every dollar that you spend getting that site up and running, it is four, five, even six dollars to keep that site really viable, to make it an asset for your company and to get people to visit it again and again. We've found, in fact, not surprisingly, that over time what you get out of this experience is in direct proportion to what you put in.

I talked a lot about reinventing some of the ways that we do business. I want to give you an example of that now that really touches on the areas of content development — keeping content up to date — and then managing through some of the effects, the domino effects that your electronic efforts have on the rest of your organization.

And I'm going to use an example. How many people here, just out of curiosity, are in the mutual fund business? Do we have anybody here? Okay. I'm going to assume that a lot of the rest of you are investors, so that at one time or another in your lives you've seen one of these documents, a prospectus for a mutual fund. Not one of the most interesting documents put out by the mutual fund industry, but probably the most important; certainly the most highly-scrutinized by the regulators. And Fidelity, as a direct marketer, is required to provide this document to potential investors before they can put a dime into the mutual fund in question. In this case, it's our Blue Chip Growth Fund.

Now, we wanted to deliver prospectuses on-line. We wanted our customers to be able to download them and take action on their investment decisions right there and then. We could have put this document on-line; you can see we just scanned it up here. We could have done the equivalent and put it out on the Net, but it wouldn't have worked.

So what we did was we had to completely — in concert with the regulators — rethink the way that we delivered this legally-required, very inflexible information. And so we undertook, with the folks in Washington, a project that would enable us to completely redesign mutual fund prospectuses for an electronic world. And you can see that we did things as simple as take what had been a two-column document and make it essentially a one-column document. We did things as useful as take the whole table of contents for the document, which is over to the left of the forward image, and make that all hypertext so that a user can jump to any section that's of particular interest to him or her and not have to scroll through the entire document.

And clearly, when we're sending one of these prospectuses through the mail, if the U.S. Postal Service actually delivers it on the other end, what we've sent is what an investor gets. The sort of analogous thing that we've had to do in the electronic world is essentially write/protect these documents, so that what we send is what an investor gets.

I should tell you that we have about fifty of these prospectuses up on-line right now, which is something less than a third of the total number of mutual funds that Fidelity offers. A dozen or more of those are updated or annually revised every month. And frankly, if we don't deliver the right version of the prospectus to investors we're out of business, we're shut down by the SEC. So clearly this updating effort has required a fairly significant investment in systems and in people to manage that update.

We've also had sort of a larger ripple effect throughout the organization that has touched on our legal organization, our customer service organization and our advertising agencies, both our internal agency and the external agencies with which we work. We've had to change entirely the way these parts of the organization look at content.

Back in 1992 for example, when we first launched our Prodigy site we had 800 screens, and what that meant to the legal department was that they had to look at 800 pieces of paper, because they didn't review things on-line then. They actually had to have everything printed out and they had to file with the National Association of Securities Dealers paper copies of all of the materials that we put out, despite the fact that they were on-line.

We've been able to change that process entirely so that all of our attorneys are reviewing documents on-line, and reviewing them very quickly. It takes many, many days to review 800 pages; just the paper-shuffling alone accounts for a couple of those days. Doing the reviews on-line has meant that we have been able to get very fast turnaround, and we have been able to respond to issues and get new content up within an hour or two on some occasions.

Our customer service representatives occasionally get calls from people who have looked at our Web site and want to follow-up with a personal conversation. It's not a matter of having a stack of brochures at their desk at this point; they have to be on-line and constantly looking at all of the content that we have out there so that they're well-versed in everything

available to our investors. And in many cases, the information that we're making available to our investors on-line approaches the level of detail that we make available to our representatives.

And then, finally, our advertising agencies have learned to work in a new way. The combination today to develop good electronic content is not an art director and a copywriter; it's an art director, it's a copywriter, it's a producer and it's a developer. They're all connected and work in teams in that sort of cross-technology.

All of this, the application of technology to the infrastructure, has resulted in a compressed turnaround. We wouldn't say that we've been entirely successful on this, but we've made a good start in being very responsive in putting very current and up-to-date information on-line for the benefit of our customers.

Clearly, in reorganizing we've had to pay a lot of attention to better integration internally. And I think we've addressed that.

The other thing that we've had to do in terms of reorganizing and reorienting jobs is really adopt a very different approach to developing content. We don't have a lot of people developing ads at this point; what we have done — and this may work for you, and it may not, there are a number of different solutions — is we've adopted something of a newsroom approach to content generation and development at this point.

And it looks something like this. We have meetings on Mondays, at which assignments are handed out. Everyone in the electronic marketing group and several of the satellite operations that work with us has a particular beat and is backed up by somebody else who can cover that beat. Based on consumer feedback that we get to our site — and we get several e-mails a week from people commenting good and bad on our site — based on information that we know is going on, things that we know are going on in the corporation, or general investment information, we develop an editorial calendar for the week and the beat people are responsible for pushing that content that gets developed through the channels, staging it and ultimately publishing it within some very short time-frame.

We've found that this gets us a lot closer to the customer, because it's so much more immediate. We're able to respond to their needs and complete that feedback loop so much more quickly than we can through the traditional channels.

So we're pretty comfortable that what we've done is get a good start on our Internet experience. It's a long-term commitment. Fidelity views the Web site as a distinct and important corporate asset, and it's something that we'll continue to put a fair amount of investment against. We'll continue to try to climb that learning curve.

So how have we done so far? We feel the same way that all of you who operate Web sites no doubt feel, which is that hits only tell a part of the story. I'm going to show you a little bit of this information, because it's pretty much the best that we have, and then get into a little bit more detail.

We have been extremely satisfied with the level of activity. After the first few months of sort of building we got to the level where we were averaging around 500,000 hits a month. We peaked in August, which is, interestingly enough, when we put our prospectuses on-line, and that really increased the traffic and the value of the site to people. We would expect to see another peak next month when we put a whole lot more of our prospectuses on-line.

Interestingly, we found that the traffic patterns on the Net are very interesting. There is a time when pretty much everybody in the country is sleeping, and the East Coast wakes up. And you see the traffic build throughout the morning hours as people across the country are getting into their offices and logging-on. And we find that we get a lot of that traffic from people's office locations.

At the same time we're finding that the on-line services browsers are really broadening the audience for the Internet, and I'm sure you've all seen that. Here are the top five subdomains or locations from which people are entering our site right now, and you obviously can see that prominent among those top five are the three largest on-line services. So their browsers have brought a whole new population of people to the Web. A lot of those people happen to be investors, which makes us real happy. So that's what has been in it for us. We've seen we obviously also capture lead information and conversion information, and without revealing to you the specific numbers I can tell you that the conversion ratios of new business to leads on the Web exceed those for virtually anything else that we spend money at this point, which may surprise you.

I want to show you a little bit about what's in it for a visitor to our site. I had alluded earlier to the fact that we've compressed a several-day investment decision-making process down to minutes in many cases, and this will give you an example. I'm going to play the role of an average visitor to the Fidelity Investments site, and I'll try to tell you along the way how we would handle this type of an interaction in the traditional media to give you a sense of the different timelines.

Visitors to our site need only type in www.fid-inv.com, and this is what he or she will see. As the investor — let's say am interested in sending a child to college. So I scan the on-line table of contents, if you will, and I choose to go into the section sort of in the center of all of those blocks called "Investment and Retirement Planning." Investment planning seems to make sense to me for what I'm interested in.

I get here and I start to look at the planning tools that Fidelity has offered, and here it is. Here's a cost calculator for college savings, and that will give me a sense for how much money I need to put aside to send my daughter to school. I input a couple of very simple pieces of information at this point.

Now, contrast this to what we've just done, where somebody calls Fidelity and asks for some help on college planning, and one of our financial representatives sends an order to Covington, Kentucky to have the paper version of this mailed out. Three or four days later that will arrive in somebody's home.

I'm able to fill this out on-line and start to make some decisions. Let's say it's several years before my daughter is going to matriculate, and so I decide that I'm interested in growth as my investment objective. I'll invest a little bit now, and with luck that will grow to be exactly what I need to foot the tuition bill several years from now. I see that Fidelity has presented as one of my options the Fidelity Blue Chip Fund, and I can at this point go into the mutual fund database and get a full range of current information about this fund.

Contrast that to the traditional environment, where I've received the worksheet on paper at this point, I've worked through it, and I've made my investment decision — I think, maybe, it's the Blue Chip Fund. Now I have to call Fidelity again and have them send me information about Blue Chip Fund.

Here, in the same on-line session, I can take a look at the fund. I had mentioned that I'm interested in growth, so I chart the historical growth of the fund. I take a look at some of the returns in tabular form. Looks pretty good to me. What I'd like to do at this point is get a prospectus, so I see from reading here that I can receive a prospectus by mail, or I can download it. I feel pretty comfortable that I've pretty much made my decision at this point, so I want to download the prospectus. We're back where we were earlier, and I'm ready to fill out an on-line application.

Several days later, had I done this by phone, that application and that prospectus would arrive in the mail. So what used to take days is now taking minutes for our investors.

I think you can see that from our standpoint, what we're trying to do is tabulate hits, tabulate leads and tabulate conversions, but we're really trying to focus on the customer's experience. We, as I mentioned, get several hundred e-mail comments a week in response to our request that visitors to our site tell us what they're thinking — what's good about the site, what they don't like about the site, what they'd like to see that isn't there right now. And we look at all of those comments and respond to them where appropriate.

Here's a couple of examples, and I'm sure it's not a surprise to you that I would show a very favorable one first. And so this one goes something like this: "I like your page quite a lot. You know, yadda, yadda, yadda. Please make more prospectuses available on-line." Done. This is easy. We'll have in the next six weeks to eight weeks all of our prospectuses for nearly two hundred funds on-line. This is simple. It tells us something is working. It tells us if we do more, we'll probably do more business.

One not so positive. "The text on your headers and footers is difficult to read. Can you do anything about this?" Well, of course we can do something about this, and thank you for asking. We said, "Okay, well this guy just doesn't like the color yellow." We got the comment again and we said, "Well, somebody else doesn't like the color yellow." We got it twenty times, and we said, "The color yellow doesn't work. Let's change it."

And so you can see that this kind of thing is very simple to do. It's very simple to invite this feedback. All of us no doubt are on-line. We know how happy we are to provide feedback when people ask, and this is real important to putting together a good experience for your customers. Listen to what they're telling you. It doesn't require a lot of costly research and it doesn't require the consumption of enormous amounts of time; you can build it right into your site and make it really useful and simple for people.

We've been very happy so far. It's never enough. What we've tasted over the last nine months has just whetted our appetite to do more on the Web. There are a couple of areas that we're going to be focusing on in 1996.

New content. I've tried to express how important the content development and maintenance process is, and the commitment that one makes when one puts a Web site up. We're going to continue to try to leverage the resources at hand at Fidelity to do more and more sophisticated interactive planning tools, for one thing.

Focus more on news and current events to make the site most relevant to investors. We're going to enhance electronic communications. We invite the comments today on the commercial on-line services and we engage in two-way e-mail and have a pretty extensive e-mail support team that responds to all of those e-mails down in Dallas. You can look for us to do a lot more with e-mail and other forms of electronic communication to really realize the promise of the electronic community that you can create on-line.

There's been some talk this morning — no doubt there's been talk at other conferences that you've been to — about how preeminent the importance of the brand becomes in the electronic world, because the electronic world is, of course, so democratic. Fidelity may be the biggest company in our industry, but your computer screen doesn't get any bigger, just because you have Fidelity's Home Page up, than it would for one of our smaller competitors. That, fostering that community and that sense of belongingness among your customers, is very important. And so you can look for us to do a lot more in the area of electronic communications.

And then, finally, transactions. We don't do transactions on the Internet and the commercial on-line services today don't do financial transactions. We do have our own private on-line service through which our investors can trade if they wish, and we're clearly very interested in and committed to offering account access and transaction functionality on-line to our investors.

But the way we look at it is this; we've spent fifty years building a trust with our customers. In the case of transactions on-line, to us it's more important to be right than to be first. The business risks that a company of our size and scope, and a company that comes under the scrutiny that we do, are just too high to go out there blindly right now.

Nonetheless, we continue to work for that day that we can pull the switch and be offering our customers direct access through the Internet.

Thanks so much. I'd be happy to answer any questions as I know my fellow panelists would.

Tim Duncan: We'll take some questions for the panel. Before we do, I was handed a note from Mecklermedia, the sponsor of the conference at break, stating that they're very sorry about the lack of coffee. If you are willing to go by their booth out on the floor and sign a short affidavit that you were unable to obtain coffee at this session, they will be happy to give you a free copy of the August 15th issue of WebWeek.

M: [inaudible]

Tim Duncan: I'm sorry. You're going to have to speak up very loudly.

M: [inaudible]

Mary Ruth Moran: Okay. The question, for those of you who didn't hear, is if a visitor to our site uses some of the information there, perhaps fills out a couple of the planning tools but doesn't choose to invest or to request additional information at that point, how do we follow-up with him or her? And the answer is, we don't.

This was an issue that we really had to think long and hard about. Obviously, being marketers we are hungry for every piece of information we can get about anybody who ever expresses interest in us; on the other side of that coin, however, was our concern that people would feel that their privacy was being violated, and they wouldn't give free reign to their impulse to go in and sort of shop around if they believed that they we were collecting data on their every move. And so we very deliberately do not do that.

M: [inaudible]

Mary Ruth Moran: You absolutely do. The business model on which Fidelity is built is that investors make their own best investment decisions. They are self-directed. They tell us when we can help. Now, that having been said, we obviously spend a fair amount of money advertising to get all of you to think of us when you're going to make an investment decision, but it's up to you to contact us.

W: [inaudible]

Mary Ruth Moran: I'll repeat the question.

W: You mentioned downloading a prospectus and filling out an application on-line, then you said you don't do transactions.

Mary Ruth Moran: Right.

W: How do those two fit together?

Mary Ruth Moran: They fit together in what is something of an unhappy marriage, to tell you the truth. This question is sort of near and dear to my heart. The question is, you can download a prospectus and you can fill out an on-line application, but if Fidelity isn't doing transactions how does that square?

And the answer is simply, yes, you can download the prospectus. Yes, you can get an application on-line. You cannot transmit it to us on-line. And so we can take the on-line experience right up until that point. And then, guess what? Until the regulators will allow us to recognize digital signatures, and until we're comfortable with the security, you have to print that application out and send it to us.

Tim Duncan: How about right here.

M: Again, a question for Mary Ruth. You mentioned Fidelity is on the Web. I'm curious about your [inaudible] on those four [inaudible].

Mary Ruth Moran: The question has to do with Fidelity's position being ubiquitous through the electronic channels. What is the relative investment on the Web versus the commercial on-line services that I mentioned that we also have a presence on?

It's actually been an interesting issue for us. When we first began, our view was to offer equivalent content on all of the channels and to be indifferent to which channel a customer or prospect chose to reach us on, not to make that choice or force a choice on people but to give them comparable information across all of the channels. When the commercial on-line services introduced their browsers, that sort of changed the paradigm a little bit. And I think what we've done, generally, is put comparable information across the commercial on-line services and then take that information one level deeper on the Internet, generally speaking, so that somebody can get a base level of information there, and it's pretty comprehensive on the commercial on-line services. If he or she wants to dig deeper, we are essentially a click away through the on-line browsers.

Tim Duncan: How about right there.

M: For Fidelity and for First Albany, this extra four to six dollars that you're spending to maintain sites; where do you spend that money? On content development? On technology?

Giles McNamee: Go ahead. You get to go first.

Mary Ruth Moran: Where do the extra four to six dollars go that you spend for every dollar you spend in investment? Is it content? Is it technology? What is it?

You know, technology is a wonderful thing and anybody who ever thinks it will replace people in the business world is sadly mistaken. The single largest expense and the largest cost item in that four to six dollars is people who know how to run a Web site, frankly. People will always be important to this, to this equation. We can take people out of the sort of routine interactions and let our customers interact directly with us through inquiring, ultimately transacting business, routine and repetitive business, but we'll have just a different set of people who will be developing and maintaining our Web site and our other on-line presences.

That having been said, the second biggest item in our experience has been content development. It does cost money. That's not a reason not to start, if you don't have a lot of

money to fund this, because you can, as all of the panelists have said, start very small with some small applications. But you will be making a long-term investment to enhance your site over time, and content costs money. Technology is the last of those items.

Giles McNamee: In our case, our efforts are nothing like as aggressive as Fidelity's. The most sophisticated things we're doing are targeted to a specific set of people who are already clients, and we're delivering to them something they've actually previously asked for, which was access to our databases. That requires significantly less effort in terms of content development. We've already spent the money building the content, and the *Internotes* allows it to be regularly refreshed onto the Web so that it's basically always up-to-date. The hardware and software components that go around the process, are a never-ending opportunity to write checks.

John Guerster: One of the interesting things that I've found in the last sixty days, that's been very surprising, is that people have come to us looking for content. They've got no mechanism as Fidelity has developed internally to develop content and information to keep their sites fresh, so they're beginning to ask us to try and develop that for them. And one of the things I'm coming to believe is that the next decade for financial services firms — information may be sort of the toaster of the next decade. People are going to come to you for information, and that's going to be your giveaway.

Tim Duncan: How about right there?

Giles McNamee: We'd like to get paid for it. That's our business.

M: I believe you said that there was a centralized area that receives and processes your e-mail or responds to e-mail. What is the background in grooming people who work there, and is there a particular program that's used, and what are the legal implications for returning e-mail, providing first a home-based [inaudible]?

Mary Ruth Moran: I had mentioned that we have an e-mail response team down in Dallas. The question was, what type of people staff that organization? How have we trained them? Have we trained them? And what are some of the regulatory and legal implications of e-mail correspondence with investors?

It's interesting. The skill set that an e-mail rep at Fidelity needs to have is not unlike that of a telephone rep or a branch rep in the sense of command of knowledge of investing and of Fidelity's investment products. But then there is a divergence. There are some people who are very good interpersonally on the phone or face to face, and then there are some people who are better correspondents in writing, and can express their ideas better and articulate thoughts better on paper, or in this case through e-mail. And so we try to select people for that e-mail operation who exhibit that latter set of characteristics. They go through the same training that our telephone and branch reps do in terms of the investment markets and command of the product set that Fidelity offers. They go through supplemental training to help them in the use the power of the written word. And so there is a fairly specific training module that they also go through.

In terms of the regulatory and legal impact of e-mail correspondence, those of you in a business regulated by the securities regulators may not be surprised, but rather chagrined, to hear this, and that is that e-mail communication is viewed still by the regulators as written communication and is subject to the regulations governing written communication, which are

frankly a lot more stringent and difficult to adhere to than verbal communication between a rep and a customer.

In fact, every single e-mail that we send out to a customer has to be reviewed by a rep who has certain securities registrations. In this case, it's a series 8 registration, and so our team managers have to be series 8 registered. And all of that correspondence, believe it or not, still has to be filed with the regulators after the fact.

Tim Duncan: We've got time for two more questions. How about way back in the red?

W: My question to Fidelity first of all, [inaudible].

Mary Ruth Moran: Do you want to go first or do you want me to?

Giles McNamee: Sure, I'll go first. The question was, if we won't talk about money we spent, what's the size of the staff that put together the pages and maintains them?

In our case the number of people that put it together is about five or six, but that doesn't count the people who are involved in the other... As I said before, we use Lotus Notes. In the *Internotes* process there's another three or four people who were involved in connecting Notes to *Internotes*, which took about a week of their time, and then they're out of the loop. And in terms of maintaining it, we currently have three people who's full-time job is to maintain it. But having heard this discussion, my guess is that we probably will need some more bodies. But we need more hardware and software too.

Mary Ruth Moran: In Fidelity's case, the number of people who maintain our Internet Home Page today goes something like this: the entire staff of the electronic marketing group, which is sort of the business line responsibility for all of the electronic products and channels, is something on the order of fifteen people now. Just one of those people is the Internet business manager, and his work is largely with a set of developers. And Ralph, how many developers would you say that we've had working day to day on the Net at this point?

[Ralph]: Probably, like you said, there's a variety of people. You know, three or four work everyday on [inaudible]. Then there's a whole other group of [inaudible].

Mary Ruth Moran: And that's just on the development side. Ralph was telling us is three to four developers on a day-to-day basis. We have an interactive marketing group in our Fidelity advertising agency, and there are three people down there on any given day who are working on the Internet Home Page. And we have one full-time dedicated resource in our legal operation. So all told, on any given day, there are eight to ten people just working full-time, 8:00 to 5:00 on the Internet.

Tim Duncan: Last question.

M: What do you think about the [inaudible]?

Tim Duncan: Jonathan, how about you?

John Guerster: Yeah, the question as I understood it was, what do you think about the reasoning for delivering payments with something like cybercash or digicash? Is that right?

I guess our view on the cash side is probably, from a vendor perspective, that we see cybercash or digicash, or First Virtual, for instance, as being alternative payment technologies. And so our model is that to offer value, they'll be used and we should support them. But there's a game in the world of electronic cash versus real cash that is being played right now in the securities space, and I think, to the degree to which consumers feel comfortable with one versus the other, that is the degree to which one of those will be successful or all of them.

Tim Duncan: Thank you for coming.

INTERNET FINANCE FINANCING AND GROWTH STRATEGIES IN THE INTERNET BUSINESS

Mark Walsh
Senior Vice President, General Manager, America Online

Timothy Duncan: Bill Bradley, the Senator, tells the story about being a guest at a testimonial dinner in his honor, and it was before people were to speak, while people were having dinner, and the guy came around the dinner table passing out the little pats of butter for the rolls, and Bradley got his pat of butter and said, "May I have another pat of butter?" And the guy handing out the butter said, "No."

The host for the testimonial dinner was sitting next to Bill Bradley and he was quite embarrassed, of course, and said to the guy handing out the butter, "Do you know who this is?"

And the guy handing out the butter said, "No."

He said, "Well, this is Senator William Bradley, and he's a graduate of Princeton University, where he was an All-American basketball player. He was a Rhodes Scholar, played professional basketball for fourteen years, led his team to the National Championship, was named to the All-Star team twelve out of his fourteen years, was elected to the Senate for three consecutive terms and is a likely candidate for President in the next election."

The guy handing out the butter looked at him and said, "Do you know who I am?"

And the host of the dinner said, "No."

He said, "I'm the guy that hands out the butter."

Which struck me, when I heard it, as a metaphor for a lot of Internet-related businesses. Seems a lot of people are trying to be the next Microsoft, and they, in fact, end up being more the guy handing out the butter.

But we're going to talk about that today, and I get to do my own little infomercial here, so I'll do that quickly and give you my points of view as a participant in a relatively new Internet-related venture, and then we'll get on with some of the other speakers. But this is what it all pretty much gets down to, as far as I'm concerned. I would suppose that's kind of a question that most of you want to ask today and have answered: How do you get an Internet-related business worth ten million dollars by 1996? And I'm going to have an answer for you in about ninety seconds.

First of all, What I do, my company, The Duncan Resource Group, is an Internet finance network. Its focus is basically to be a center, a place on the Internet whose sole purpose is to serve a vertical market, a very strictly-defined vertical market, and that is people that work in the fields of corporate and commercial finance. It's for professionals, for people whose business is finance. We started out with a directory, primarily to attract an audience, which we succeeded in doing. It's a directory comprised primarily of sites related to and of interest to our target audience, with some additional concept described in those sites, and the services and products that those companies produce.

We also do consulting with financial service firms to provide them with Web site design and maintenance in strategic partnerships in that specific sector, as well.

Eventually, we hope to be delivering content. We actually will be delivering content next month, in conjunction with Securities Data Corporation. We're going to be publishing weekly summaries of IPO and M&A activity across the United States, and then a monthly and quarterly wrap-up of different activities, investment banks and commercial banks around the country.

Our objectives as a business are primarily to attract a target audience in a specific, vertical business market; to learn what that audience wants from its use of the Internet and help our clients sell to that audience; and then, eventually, to help our clients transact business over the Internet.

We are, in effect, in the content business, and for you folks out there that are in that business or considering it, from what I've learned, the advice I would give you is that despite all the hoopla and hurrahs about this business any start-up still requires time and capital; and I'm amazed sometimes that I've talked to a lot of people that have been in business now for three to six months and are complaining because they're still not making money. It's a long, slow swim underwater, whether you're in an Internet business or another business, if you're going to begin a start-up.

I think primary revenue generation today in Internet-related business, if you're in the content area, is going to be from providing your clients with education and know-how. Revenue generation, I believe, is really something that's not going to come for quite a while — at least eighteen to twenty-four months before anybody can meaningfully raise revenue of their existing business on-line, with a possible exception of Internet-related, software-related products.

I think this is an information business. It's not entertainment business, and I think — as I go on and on — that I'm more and more convinced that this is something that's just essential to be successful in a content-related start-up. We're starting, in the last sixty to ninety days, to get more and more requests from our clients in the financial service businesses, that they need to be able to produce more information on-line in their own Web sites. They need to produce content; and in fact, I'm coming to believe that information in the financial services business and in other industries will essentially become the toasters of the next decade — and that's what I have to offer.

So, back to my question, my original question, "How do you get an Internet-related business worth ten million dollars for 1996?" You invest twenty million in 1995.

Our first speaker is Mark Walsh, and Mark is the Senior Vice President of AOL Enterprise. He's basically the business-to-business guy at AOL. He came to AOL via a very highly-reported executive recruitment in the Spring from GD Genie, where he had been the President of that group. Before that he was Vice President and General Manager of Interactive Services at CUC International, and part of that he was in charge of new business development at HBO. Mark has a B.A. from Union College, and M.B.A. from Harvard Business School. He tells me he dances well, he's a real swell guy and a very delightful speaker — Mark Walsh.

Mark Walsh: Verbal dancing will be the specialty today. I'm not the butter guy, I'm the bread guy.

I'm interested if I could just a sense of the crowd: How many people here belong to one of the major on-line commercial services? How many people here belong to AOL? For those of you who don't, please give me your home address and we have the planes fly over your house and bombard it with disks for the next few weeks. Happy to do that. How many people have heard me speak, so I know which jokes not to use? Okay.

Today's talk, I think, is going to be a fascinating one for a four-hour stint. I'm very much in appreciation for you people for showing up for a four-hour talk; I sort of thought it was some misprint. By the way, we're going to lock the doors and no one is allowed to leave for four hours, just so you know. So, you will learn in the next four hours.

I think a portion of what I'm going to try and cover — and I hope that at the end of the day you will feel you've gotten some delivery on, if Tim's done his job as far as the guest list — is feeling a little bit about what the future is going to hold for us all, particularly from the financial side of the house. As Samuel Goldwyn, the ubiquitous Hollywood producer once said: "Never make predictions, especially about the future," and effectively I think we're all in the same boat right now, which is that we're making predictions about a business which is not only unpredictable, it is beyond predictability.

I felt as I walked the halls and the paths of booths out there today, lovingly I say it was almost like sort of a "random claim" generator, that whatever the booth was there was a random series of phrases like Empowerment, Site Creation, Maintenance, Applicable Tools, whatever, and it's so confusing to even those of us in the business that you can imagine what businesses and consumers find about this industry. And until we're able to describe ourselves in more cogent and taut terms, I think we'll all have the same types of problems, which is that we're an idea whose time, perhaps, has not yet come, or that is coming in ways we can't predict, and will be of service to consumers and businesses in ways that we will find out almost after the fact.

But my topic today is to talk about getting money to start companies. Getting money to grow your company. Getting money to cash in on what some argue is truly one of the larger new business ways to hit the American, or perhaps the world business cycle, in three, four, five, some say eight or nine decades. It's a pretty big claim. I spoke with one of the America Online's largest shareholders today. He, of course, is always right, just so you know, and I continue to remind him about that, and he suggested that by the year 2000, there will be two-hundred million e-mail accounts, worldwide — two-hundred million e-mail accounts. He went through the math and at first I scoffed at his number, but as he went through the math and how he reached that number, it actually made some sense, which just goes to show you how the math in this business can sometimes make sense in ways that is surprising and scoffable prior to your going through the exercise.

But America Online has, in the last year, exhibited a lot of the behavior sets that you'd like to see from the outside of investing in and trying to grow content or connectivity or software types of business that help its goals — and, I believe, also help the industry. AOL is a company that has grown about a thousand percent in the last two to two-and-a-half years. That's fun and sort of not so fun at the same time.

I've got a couple of jokes about AOL. I've been there six months. One is that really the job there is you show up and find the desk and a phone and then make up your job for the day and go home and make it up the next day, that there's sort of so much opportunity, so much going on, that there's no predictability about your own job content, and I am proof of that. I've had three and four jobs in six months.

The other is that at AOL, if you took fifteen random people from the company, lined them up against the wall and interviewed all fifteen, two or three of them would have the exact same job, but wouldn't know about the other people. That's a function of a high-growth company. I think it is not something if you're a shareholder to be worried about. However, it does imply something that I think all of us in this room share, which is what as the fighter pilots like to say when they were surrounded by enemy planes, "I'm in a target-rich environment."

We are in a target-rich environment today. We have been for the last year or so, and I would suggest that we are in a maximum target-rich environment for the next thirty-six to forty-eight months. But, what are the targets? Are the targets better and cheaper connectivity? Well, I think the term by [Russ Siegelman] of death-spiral pricing for connectivity, he of the Microsoft Network, is correct. Connectivity will be a very difficult business to make decent, defensible margins in.

Are we in the business of software? Well, there are those who argue that the browser and the other production style Web site creation software business will be difficult, because no matter what kind of browser you come out with, someone will come out with a better browser. Standards are still unclear. The standard-setting bodies are, perhaps, being slightly shunted aside by very aggressive corporations that are making very aggressive investments and setting their own standard set; and I have no quarrel with any of this behavior, it's just the nature of the beast.

So, the third [point is] content. Is that where we can make a difference? Is that where a target-rich environment exists today? I would suggest, yes. That the content business, or the manipulation of an attractive presentation of preexisting content, is where a lot of the investment dollars will ultimately flow in the on-line services business — be it Internet based or proprietary consumer services, like AOL.

For the sake of this talk I'm going to stop making the distinction between Internet-based and proprietary consumer services like AOL, because our new 2.6 software has full Web-browser capability built into it. Our major competitors, Prodigy, CompuServe, etc., all now have Internet outreach. So, you may argue with the software, and how closed the systems are — closed is bad, open is good — but I'll stop making that distinction, because frankly it will make the speech too difficult to comprehend.

But let me talk about how target-rich opportunities for content developers or presentation packagers of preexisting content can happen at America Online. Then I'll make a few short observations about where future investments and opportunities might be, and then I'll hand it over to folks in the panel forum who are better able to finance things than I.

Today, we have an ongoing investment fund, and there's a natural place to put it called the "AOL Greenhouse." The AOL Greenhouse — in your program, just to helpfully alleviate confusion, it mentions that I will talk about Indians and Buffalo — what I meant by that when I wrote that down was that the Indians, American Indians, when they killed the buffalo, were famous for being efficient in the use of all pieces of the buffalo. They carved out the horns and made drinking vessels of it, they used the hide as blankets, the obviously ate all the meat. They used the hoofs and the legs and the bones for a wide variety of uses. They were ultra-efficient in the use of the beast after they killed it.

The American Cowboy, in his infinite wisdom sort of riding across the range, would just shoot buffalo for sport, from trains and horses, just kill them; and it struck me that what AOL was trying to do with Greenhouse was become more "American Indian-like" in its ability to be more efficient in using relationships or building relationships with content providers, that it could may be put up AOL on a place on the Web and get other visitors from outside of the AOL world to visit them, and be more efficient in the distribution of and the making money off of the content. So, the AOL Greenhouse is a way to do that.

We've done about twelve deals so far with individual entrepreneurs and groups of people, who receive checks from AOL ranging from the low to the high six figures, that's typically the range that we look in. AOL typically receives a piece of the equity or some sort of cash, a guaranteed cash stream from the company in response for its investment; and frankly in its investment program it says: "For the money, you get started and I'll give you access on AOL." So the four million members, or eight million eyeballs that is AOL — or approaching eight million eyeballs that is AOL — is sort of natural distribution for the content provider to start off with.

Secondly, AOL has been very active in purchasing companies. When your stock is at a "P" rate that is like ours, it's very aggressive. You have the ability to purchase companies with stock, and the owners of the companies are very happy to take it; and it's a matter of public record that we've given a lot of AOL stock to a number of corporate owners, company owners and individual entrepreneurs who started companies like WebCrawler and GNN and Web Soft and WAIS, and Redgate and others, Meteor, who have received AOL stock in a pure investment or purchase play. They are now part of the America Online family of companies or they're part of America Online, and that stock investment, with some cash kicker, typically is another rational way that we acquire companies to make ourselves grow stronger.

The last and the hardest to describe in the investment world today is what is typically monitored, [and that's] joint ventures. Joint ventures are a little bit like the six blind men and the elephant. One grabs the tail, one grabs the trunk, one grabs the leg. To each of those people, the elephant is a different animal; and I think if we canvass all the folks in this room and ask them what a joint venture was, you get a lot of different answers — and I think that's good, that's what a joint venture should be. It should be the result of hard and serious and — hopefully — friendly negotiation between the two sides, where the money is shared, where the equity potential is shared, future equity is shared, potentially creating a new entity that both companies invest in. All of these models are being used, or certainly discussed and played out within AOL now, with companies that we're discussing and sort of placing our lot together with.

Now, what does this kind of corporate behavior mean for the industry? I know AOL is certainly not alone in these types of models of outright purchase, investing in small growth companies and joint venturing. Every single on-line service out there, every single one that is in the consumer on-line service that's in the marketplace today, has something similar to this. Prodigy just recently announced a Greenhouse-like — we think from what we could read in the press release — a Greenhouse-like effort to initiate and grow an entrepreneurial content provider relationship. So, there's nothing new under the sun here.

But what does this mean to the marketplace? As we reach out to entrepreneurs, we reach out to divisions of larger companies who want to split off a division that maybe isn't getting the kind of entrepreneurial support that it needs. What does this mean for the consolidation, which many say will ultimately come? When Alexander Graham Bell invented the telephone, there sprang up about three hundred and fifty telephone companies in the United States. About sixty years ago, there were about fifty car companies in the U.S.

My conclusion is not necessarily to suggest that of those fifty, forty-seven were wrong; but Darwin was right, and when Darwin said only the strong survive it does not necessarily mean size. In the same sixty years since fifty car companies disappeared, many other massive, powerful market-dominant American corporations in a wide variety of fields — retailing, computing, communications, transportation — have also failed, and smaller companies have grown. So my implication of saying Darwin was right is in no way meant to imply that our size or market momentum is a protective barrier, and smaller companies must come to us in a state of supplication and we will deign to give them some attention.

There are companies out there making less than five million dollars a year who three years from today will be some of the dominant companies out on that platform and out on that floor. So, the idea of Darwinism being correct, to me only implies one thing, and here's the small piece of advice I will give. Whatever it is that you or your company do for a living, I would suggest, if you can't describe it in under two minutes, then it ain't a business.

And I mean in no way to criticize, but as I mentioned, going around these booths it's a random claim generator. The Internet and all of its opportunity makes us use jargon so much that a lot of our business plans and our focuses become very diffuse. So there's nichemanship. Although sometimes it's difficult to suggest, "Gee, I'm in a niche business," nichemanship really is the secret of what's going to happen here.

The last two things I'd like to suggest are: One, planning. If you ever feel that there is some master plan from deep, dark executives sitting in some large tower who know where this all will go, rethink your thinking. We are all making this up — all of us. This industry, this platform, this set of consumers, this set of constituencies, these sets of software tools, these sets of connectivity solutions, are all brand new. All of you will hear and try to have models applied to you, just like the cable business, just like the telephone business, just like the railroad business. There is no business just like the business we're in. The only business where in is change; and I don't personally remember, looking back on American business, a time when change in one industry was so dominant a theme.

F. Scott Fitzgerald was once asked what it's like to become poor. He became quite poor at the end of his life, and he said, "First, it happens very slowly, then it happens very suddenly." We have had a slow period of three to five years of growth of the Net, growth of the browser business, growth of on-line services, growth of content providers; and now we are starting to go vertical, and I would only suggest that if you are in the business of trying to start an on-line service business, be it content, connectivity or software, that you at least consider speaking with America Online either in Greenhouse or in our venture development side, or in our sort of joint venture type of model as a partner to help you grow that business.

And with that, I will thank you for your attention and, I guess, take your questions later.

Timothy Duncan: Thank you Mark. I like to be different, and every company I run into wants to be the next Microsoft or the next Netscape. So when people ask me a question: "What company will you grow up to be?" I always tell them "Goldman Sachs."

Bob Nolan, our next speaker, is the Vice President of Goldman Sachs. He's in their media technology and information group. He was one of the founding members of that group that was formed in 1992 to take advantage of the convergence of those three areas, and Goldman Sachs, in the last year, has participated in a number of very significant transactions relating to Internet-related business, including the initial public offering in May of UUNet, which they were the lead manager for. So, here is Bob Nolan.

Robert Nolan: Thank you Tim. I'm glad to hear you value Goldman Sachs so highly. I always thought America Online was the company we wanted to grow up to be. We're working on that. It is fitting that I follow Mark in his commentary, because his company does bear on a number of items we'll touch on, particularly the first one.

I thought in honor of today being Halloween — I'm rather curious as to where my children are going to trick-or-treat this evening. I was also curious to see that cyberspace has been added to the list of possible neighborhoods. The on-line service companies, such as AOL, CompuServe, Prodigy, MSN, and even access providers such as Internet MCI are all offering various treats for those adventurous souls that want to visit them this Halloween. And the feature I like the most is the one that's offered by Internet MCI that enables the user to select a

Halloween costume from the Microsoft CEO, Bill Gates. Now, I'll let each of you deal with that issue. I thought maybe a Gap jeans ad might work in this case. There are any number of potential answers to that question.

But what it does do is raise, again, the issue of an interesting application on the Net, and as always the question for those of us on Wall Street is about how many people care and how many participate. Now, if you believe the Nielsen research numbers that were out in the paper this morning, there are quite a few of us. Thirty-seven million people supposedly have access to the Internet as we speak. Half of them are age 16 to 34, and frequent users. The question, of course, for us financial types is what services will they use, and how will they pay for them; and my comments this afternoon are designed to review Wall Street's current affinity for all things Internet related and to discuss the notion of cybercommerce, its future and its ultimate acceptance as an investment concept on Wall Street. As Lee Stein, the founder of First Virtual Holdings has postulated, it may well be the beginning of the biggest market in history.

As an investment banker who has worked extensively with communication companies, media companies and networking companies, explosive growth and development of opportunity for Internet-related commerce is exciting and daunting. Other panel members this afternoon will discuss the venture capital opportunities and the private market sources of capital. My role is to discuss the public market opportunity; and with the recent successful initial public offerings by companies such as UUNet and the Internet access area, and Netscape in the Internet's software category, investors are clambering for more compelling ideas and concepts. We certainly believe that the concepts related to cybercommerce may well provide that next wave of excitement.

So let's review for a moment how we've arrived at this stage of the Internet. This is clearly one of the reasons we're all here today. It is a hot topic, one that merely confirms the notion that it is written about often and with good reason. Revolution of the industry is fairly straightforward, and you're all familiar with its academic origins; but what is really important here is with the growth of the WorldWide Web and the additional services being employed. We now enter into the major capital infusion stage, both public and private capital being utilized for many small startups — and many that were previously small have become major companies in their right.

A quick overview of the Internet. It is a global network. It obviously provides any-to-any point of connection. The real point is that it's the world's largest on-line information exchange. It is a network of seventy thousand plus disparate computer networks. It has grown from less than a million paying subs in 1994 to our projection of twenty-two to twenty-five million by 1997. The top three uses, of course, continue to be e-mail connectivity, file transfers and access to the Web.

And we see the Web as the key catalyst in the growth of the use of the Internet. Clearly, the easy point-and-click server software has been a major catalyst in that it has provided a multimedia printing press arrangement, and obviously the hyperlink is one of the real issues that will allow it to continue to grow in the future.

Now, we take a look at this market in broad form and then in six categories, and we've projected what we think the revenues are; and chances are that these are very conservative, since they bear from '94. But just to put it in context — the total market: we saw '94 revenues of little more than 800 million, growing to 4.3 billion, a 72% compounded annual growth rate. Breaking that down, first the hardware: we see it growing at roughly 60% from a '94 number of just under 500 million to almost 2 billion in '97. The expertise category, in which we include consulting, network management and support, we also see as a huge grower: 78% compounded annual growth rate, totaling 335 million in '97. Access providers, which we're going to touch on in more length, growing from a base of 135 million to 860 million in '97.

This will, clearly be the wave of the future. The software providers, and this is very conservative estimating in our mind, '94 to '97: 44% compounded annual growth rate. The service providers, which is the transaction advertising, marketing services available, we think will grow at almost 300% compounded annual growth rate: roughly 400 million as a revenue figure in '97. And, finally, of course the content providers, which may well be the mother lode ultimately: the directories, the media — 300% compounded annual growth rate.

These points are also made graphically in a bar chart. I'm not going to dwell on them. The fact of the matter is, as you look at each of the six categories, they all hold ample opportunity and I again would argue that software services and content are probably understated as we look forward. This merely looks at the access market to gauge the contribution from the consumer and the commercial side, and see them in terms of growth rates. They're both in the 80% compounded annual growth rate segment. The fact of the matter is they're both contributing mightily to the access business. We think they'll both be contributors to commercial and consumer side in many of the categories.

What do we think will drive expansion on the Internet is use. Obviously technology and culture changes, and [these] are already underway in corporate America.

Mark already touched on the lower cost that we'll see on the access side. I think we'll see it on service side as well.

The trends that we're seeing clearly are bandwidth demand, and that continues to grow; and as you'll see the uses are going to demand more bandwidth as we get into audio and video. The international acceleration has already begun on the access side that's underway with a number of acquisitions, and the consolidation of partnering intensifies both domestically and internationally, a number of fields. The demand is increasing, as we mentioned.

There are many more high-speed connections growing that are increasing. Businesses are ordering multiple connections, and the customers, not surprisingly, want bundling of services. They want a host for the Web server, and of course they're looking for security and reliability in use of the Internet.

Then we get to what the board middle-marker will be, and Mark, again, touched a bit on this concept. What is the role of the service provider, and what is the role of the Internet access provider? They both bring historically different skills to the table. But I'm not sure that hasn't blurred already, as we speak. The announcements came out yesterday on the part of AOL and the part of AT&T regarding AT&T's desire to get onto the packaging side, from just providing access, and of course AOL provides not only packaging but access. So I think we've seen a complete blurring of how we approach the marketplace going forward.

Very quickly, on the services side: we're projecting 35% subscriber growth. We expect 40% through '97, reaching more than 2 billion. I think the key point here is that it's the only industry to-date with proven experience in interactive services. There are, however, many competitors coming in this field. Microsoft Network, as you know, is underway. We think it could grow to two-and-a-half to three million subscribers — I don't mean to scare you Mark — within the next eighteen months. But many of the listed companies here, and clearly the larger ones at the bottom — IBM, MCI — already started on its path, and of course the regional holding companies, once they're freed up from long-distance restrictions, may become larger players as well.

But the uses continue to be those that we identify at the outset: e-mail, chat, forums, 50% to 75% of the usage. The people, the computer communications, content, access and of course downloading information is in the minority: 25% to 50%. I do think that as we've now developed community and developed packaged information for communities you'll see more use of the commuter communications in the future.

Now, in terms of the services blending with the open Internet, there is no question that the major services will provide Internet and Web access in '95. I think it opens up many opportunities for the service companies, mainly in the form of subscriber acquisition opportunity, from the Internet.

The problems to be solved that remain on the Internet are clearly about industrial-scale privacy. This really speaks to the corporate user. But security and reliability are primary issues. The licensing and copyright issues — I know we have some attorneys on this panel, I'll let them address it — but clearly that's an issue to be dealt with in terms of content in the future. And, of course, the last mile of bandwidth. As we identify those growth opportunities down below, audio and voice and video, there's going to be more need for greater bandwidth, and that point is made on this chart. Working from left to right, and bottom to top: e-mail and Web graphics already in place; however, we're going to have to expand the pipe as we get into audio and ultimately to full-motion video being available on the Internet, and that build out is occurring, but will take time.

Now, commercializing the Internet does make it the prototype for the information highway. This is the global and inexpensive connected computer network, and we think cybercommerce represents a great industry opportunity in terms of services for businesses and consumers, and we do see a very real future for cyberbanking and cyber-retailing.

In summary, we think that the Internet definitely affects industries on the cost and revenue side, and will increasingly do so as we produce quicker-paced information and more cost-efficient information. We do see the Web as the fourth utility for business and consumers; and we do see the companies playing a very key role, having done so early in identifying customers, packaging information, and creating critical mass of customer base.

Before we get into that graph, let me just say that as we've mentioned, the Internet has been embraced as an open network for research, communication and e-mail. The issues are straightforward regarding security, privacy and anonymity.

But how is Wall Street going to cope with these growth stories that are ahead of it? I vividly remember many of the potential investors asking us how to value a start-up company UUNet Technologies, which was at the time the first commercial-only Internet access provider to come to market — and UUNet had the obvious benefit of Microsoft backing, as they built out the infrastructure for the Microsoft Network. But how in the world were investors going to value a growth story in a fledgling industry, with potentially giant competitors such as AT&T and MCI poised into this market?

So, we thought about it — was there a traditional valuation measure to employ? Could you use a multiple of operating cash flow? There was no direct precedent. How about an earnings multiple? That was even tougher in the case of a company such as UUNet, which obviously had projected earnings a bit out, even though they have now met that projection early by a quarter. So, did you then assume a multiple of projected revenues? Even that was tough to distinguish. You have a huge growth in revenues, and the fact of the matter was that there was no benchmark that existed at the time.

Now, we at Goldman Sachs oftentimes draw value thoughts on technology growth stocks by reviewing the consensus for the projected compounded annual growth rate for the next three years of earnings. And we compare that rate oftentimes to a PE multiple, and we perform aggressive analyses on a number of technology areas that are in existence, and you'd be surprised at the remarkable similarity that exists between these three-year projected growth rates and the price earnings multiple that exists on that stock. But, of course, that didn't work in the Internet case, because we didn't have earnings.

On the other hand we could have suggested to investors that they value the investment on a discounted cash flow basis, computing venture capital type of risk and return into their

model. This is oftentimes used in a concept or idea-based stock offering. But it is a practice more commonly followed by early private investors, who often have different investment return objectives, greater returns, given the relative liquidity of private equity investment — clearly more risk. And also this valuation method is oftentimes used as a check against other valuation techniques to ensure reasonable investment objectives.

Now, as we looked at not only UUNet we looked at more subscriber-based companies such as an AOL, companies with belated earnings who we've seen in the past such as cable, paging or cellular businesses — they've often been able to rely on measures such as the number of existing subscribers, or in the case of cellular the potential customers or "pops," as a proxy for traditional valuation techniques. But the open nature of the Internet extends to competition, and there are no protected markets or monopolies as existed in cable or telephony, or even [inaudible], as existed in the case of early cellular. And thus prospective markets related to the Internet are harder to measure, given unfettered competition.

Now, I apologize for this graph a bit, because this is a very tough one to read. You'll have to take my word for it. But the third column from the left details equity market cap for a number of companies in the Internet, broadly speaking. We divided them by service companies, Internet access companies and software companies. Suffice to say we have AOL listed there, which is more than a four billion dollar equity market cap, as we speak. On the access side: UUNet, a billion and-a-half equity market cap in six months. And Netscape, of course, well more than three billion in equity market cap.

Without going into the individual multiples that appear on the page, the fact of the matter is that Wall Street values this industry on change, on growth. If you look at their three to five-year EPS growth rates, which is the column that appears to know the page, the PE multiples won't even match up with that growth rate. There are multiples of revenues, such as in the case of UUNet, thirty times projected '96 revenues. The fact of the matter is, however, that Wall Street continues to embrace the whole notion of the Internet and we see ample opportunity going forward for more of this type of valuation of the right idea and the right company.

Now, the commercial value of the Internet will become increasingly clear with a reliable and secure framework for financial transactions. Commercial interests can be extrapolated from the number of inquiries on any given Home Page or hits, as one form of success or a measure of success. But "needing convenience" will be the watchwords for consumers on the Net, and will determine the level of success in this type of market in the future. And we believe that there is a very healthy future for cybercommerce with many small companies. We think the sense of community that has already been developed on the Internet and among the service companies is continuing to grow rapidly. Thus, the first adopters of a new market and the financing techniques supporting them are already in place.

The next state, however, for cybercommerce will require broad acceptance by both merchant and buyers alike, born of necessity and convenience. A sense of community will enable both of these characteristics, and it is our bet that Wall Street will embrace this concept with the same passion, fervor and possibly even the same lofty market multiples that we've witnessed to date. Thanks.

[Tape change]

Timothy Duncan: Thank you, Bob. Our next speaker is Ollie Curme. Ollie is the Managing General Partner at Battery Ventures here in Boston, one of the medium venture capital firms in the country. Ollie is responsible for the firm's investments in the software and communications

areas, and he's here today to give the VCs, the venture capitalist's perspective on the industry and some of the issues that entrepreneurs in this industry are facing.

Oliver Curme: Thanks Tim. Can we have the first slide? There we go. My name's Ollie Curme. I'm a general partner, not yet the managing general partner.

We have slides. This isn't a computer show, it's a slide show, and so we can only point towards one screen. Sorry about that. . . I'm going to talk about the venture capital financing path, and in general how companies use venture capital to pummel their competition. But, before I get started, let me get a sense of your interests.

First off, how many people in the audience have used the Internet? Raise your hand, please. Very good. Very good. OK, I won't have to explain the Internet to you. Secondly, how many of you are interested in financing Internet businesses, raise your hand. Okay, for those of you who didn't raise your hand, this is a finance in Internet business, so you might want check and see if you're in the right place.

But how many of you are interested specifically in raising venture capital, raise your hand. Okay, well it looks like I've got quite a sales job to do, and I was a little bit afraid of this, so I've prepared an alternative presentation.

The story of George Hearst. How many of you know who George Hearst is? Good, nobody knows who George Hearst is. I will run quickly through his story, and I urge all of you to ask questions when I'm done.

What is the Internet? We all talk about it, we all use the analogies; it's hard to get up and say anything that hasn't been said before. However, I do have a favorite analogy that I use to describe the current Internet phase, beyond just mania, speculative frenzy, giant post office, data service, etc. To me the Internet is like the gold rush. Not just any gold rush, specifically the Nevada gold rush of 1859. To give you a little bit of history, there had been a previous gold rush in California in 1849, in Sacramento. But by 1859, a lot of the mines were played out and there was a huge glut of miners.

There were about 400,000 miners who were barely earning a living in the late 1850's and they were all desperate for work. One of these miners was Henry Comstock, he's the guy in the middle. In the early spring of 1859 Henry was digging in Mount Davidson, in Nevada, in an area that had already been prospected, when he hit a fabulous vein of gold which became known as the Comstock lode. This was the greatest single mineral strike in history, and this is a little painting of Ernst's rendition of what it was like when he hit the gold.

Here's a picture of Henry later on when he got rich and he could afford a top hat. Here's a picture of the mine; he had some innovative mining techniques.

Well, before you know it all the enterprising men in America took their burros and set off towards Nevada. They set out in small groups to find their fortunes, and there they are looking for gold. They formed big enterprising companies, and overnight towns sprang up in the wilderness and thriving cities appeared.

Now, I'm sure some of you are wondering what all this has to do with the Internet, so I've developed a slide that shows the parallels between 1859 and 1995. Here it is 136 years later, and to me it looks pretty similar. And recently a lot of the software markets have been played out. Big giants like Microsoft, and IBM buying up Lotus, have taken a lot of the fun out of the desktop market.

In the beginning of 1995 there were 6.5 million software developers in the United States and lots of them were hungry to find the next killer app. In 1859 we had prospectors; in 1995 we had — anybody want to hazard a guess? Preservatives. That was a trick question, sorry about that.

A rich strike was announced this year in May with PSI, and congratulations to my fellow panelist Bill Bunting, of Montgomery. This was quickly followed by NETCOM, UUNet and Spyglass. And then in July the investment glass hit the motherlode, Netscape. By now the Internet gold rush was in full swing.

In 1859, it was Pikes Peak or bust, today it is Internet or bust.

Here's an entrepreneur at 1959, and the same entrepreneur in 1995. For those of you who can't read that it's <http://www.money.com>. This graphic is courtesy of [inaudible] Group, I stole it from them — so much for intellectual property.

Here the choice claims that the entrepreneurs are going after: servers, browsers, security, authoring tools... However, guess what? These claims have already been staked out. Everybody, I mean every body has spotted the Internet opportunities and now all the big players are going after these markets. Media companies are all going after content. People like Silicon Graphics, 3D Visualization with VRML, and Dolby and Sun are trying to get a play at HTML offering tools. Visa and MasterCard and [inaudible] Netscape, Spyglass, and Netscape and browsers, RSA and Checkpoint Security, Cisco and BBM routers.

And then, of course, on the other side Microsoft has a huge appetite and is going after everything. So this brings us around to George Hearst. Remember him?

Hearst was the son of a Missouri farmer who came to California in 1850 to make his fortune. He worked unsuccessfully as a miner and then a storekeeper, and then in 1859 he was in Washo, California working a new mine when he heard about the Comstock find. He dropped everything and he headed to Comstock, where he cut a deal with one of Comstock's partners to acquire a 1/6 interest in the mine.

Now the price on the deal was \$3,000. George didn't have \$3,000, but George was smart enough to hightail it over to San Francisco and he raised the money in two weeks and hightailed it back to the mine.

It was a very early form of venture capital. It wasn't an institutional venture capital, but this guy needed money and he went out and he raised it quick. He hurried back with the money, and then the team used the money to start developing the mine. Within two months they parlayed the \$3,000 into \$90,000 of profit, taking out 38 tons of ore, which is about a 30 times return, and they plowed that back into mine development.

Now, I think you may see where I'm headed. It's towards a blatant commercial on the virtues of venture capital. But before I get to that, let me talk a little bit about Internet business models.

This is a slide that I stole from Michael Porter at the Harvard Business School. It describes the factors leading to industry computation. In the Internet, the threat of new entrance at the top is extremely high because the barriers to enter are so low. We've got 6.5 million software developers out there in the U.S.

The bargaining powers of buyers — you might read Internet surfers — is very high, because they can click in and out of your site in a manner of a second. The treatment of substitute products is also high, and the bargaining power of suppliers to the Internet business is very low. And this leads to extraordinary computation. It also leads to what I call the "generic Internet business model." This business model was pioneered by Netscape, but applies to many Internet Businesses. And basically, it's oriented towards a drive for market share. Market share above anything else, you offer extraordinary value in a product or service, you utilize the ultimate of price elasticity, which is you give the product away, and in return you build customers, you build brand, you might sell a little advertising, but the most important thing, is you try to build propitiatory standards.

And the reason for this business model is because the only way to get leverage in the Internet is in that box on the left-hand side, the bargaining power of suppliers. If you can get out

there and you can dominate an area and you can build in a propitiatory standard, then you've got leverage in terms of the bargaining power of suppliers.

There are a lot of examples of companies using this generic business model. On Web sites, there's companies like InfoSeek, ESPN, Quote.Com — we're investors in InfoSeek, it's an Internet search service. All of these companies just give away extraordinary content and they make it up, hopefully, on the advertiser.

SGI puts VRML into the public domain and tries to leverage up the propitiatory standard with VRML+. Sun with Java, Dolby Acrobat, are trying to leverage their way into HTML offering tools. Netscape gave away their *Mosaic* standard browser, and now they're building proprietary extensions.

Pipeline is a service provider, and you may have seen this ad. It's not free, but it's an extraordinary value; it's unlimited dial-up Internet access for \$20 a month, flat rate.

Here's another Michael Porter slide, and it shows that companies can make a very high return on investment. In general, by either being the market share leader, that's on the right-hand side, and dominating the market, or by following a niche market strategy.

The companies that I've talked about so far are all going for mass market share; however, it's not the only way to make money. There is some merit to owning a small niche in the market, and that's something that I'd encourage you all to think about. As a venture capitalist I'm really interested primarily in building huge companies that dominate a segment of the Internet business, not nice little small companies.

Okay, here's another quiz. What do all these companies have in common? They're big, successful Internet companies, and they all went public this year and they all lost a lot of money prior to going public. Why did they lose money? It's due to the generic Internet business model I just talked about. If you give extraordinary value away for free, you lose money.

Now, how did each of these companies finance their losses? That's right, each of these companies raised venture capital. And this brings me to the unabashed commercial.

What does raising venture capital get you? I've listed these six things. The top one is cash, and certainly the cash is very important, but cash is not the only reason to raise venture capital; in fact, if that's all you're interested in you should get it elsewhere.

Venture capital has worked very closely with our companies to recruit additional management to help position our companies in the market, to provide the resources in terms of cash and human resources to execute a crushing sales campaign. I mean, we are in the business of building small platoons into brigades, into armies, to go to war and to crush the competition. We work with our companies to establish strategic partnerships, and we help coach our companies through successful IPOs. These really are the factors that make venture capital a strategic weapon that companies use to fight their competition.

Now perhaps some of you are thinking, "well how hard is it to raise a bunch of capital?" This is a picture of the trek to the Yukon. Raising venture capital is not nearly as bad as the trek to the Yukon.

This is what it costs to raise venture capital. Just a couple of different things. In terms of time, generally it takes one to three months; if it takes a lot longer than three months you're doing something wrong, you've got the wrong pitch, you maybe shouldn't be raising venture capital.

The benefit, if you raise venture capital, after one to three months is that you get the money and you get the contacts for perhaps a six to twelve month acceleration into the market. So you get going on a faster track.

In terms of ownership, typically companies give out between 10% and 30% out of equity in their companies to the venture capitalists. So let's say 20% on average, although it varies somewhat.

What's the benefit to that? Well, if you give away 20% of your company and you get going in a market that's growing at 12% per month, or 400% per year, there's a six week payback. If you can get on a 400% growth curve six weeks faster, it's worth giving up 20% of your company to get there on that growth path. So given the extraordinary growth characteristics of the Internet, it's often worthwhile to give away a piece of the company to get going that much faster.

In terms of control, we never ask for control. You don't give control away when you raise venture money. You enter into a partnership with your venture capitalists, and the benefit is that we help build a team together and we build a group. If you want to dominate a company and run it all yourself, don't raise venture capital. But if you want to build an organization that transcends you, it's a good path.

One thing that I do want to emphasize is that it's a wonderful environment to be raising money in. The money flowing into venture capital funds have doubled from one and one-half billion dollars a year about five years ago to a little bit over three billion dollars a year these days.

Over the same period of time, over the same five years, valuations on private companies that venture capitalists have paid have doubled, from roughly ten million dollars to twenty million dollars for a small, rapidly-growing firm.

I read an article in Fortune Magazine awhile ago about Michael Milken, who was interviewed from his jail cell, and he was quoted as saying that anyone who is not raising equity in this current environment is crazy. Now, he may be a felon, but I think he's right.

Venture capital isn't the only source of capital for private companies you can still raise money from a variety of other sources. A "bootstrapping" is just what we call raising cash internally, and it makes sense for small niche markets, or even certain OEM markets that don't have a big marketing cost.

DDL, does anyone know what DDL is? It's a term of the art that we use in the industry it stands for doctors, dentists, lawyers — it stands for rich guys. Rich friends and family are a better way for most people to raise money than venture capital. Perhaps 10 to 100 times the amount of money is raised through DDL for start up companies in the U.S. than through institutional sources.

Corporate partnerships. This is a very fertile area, especially these days with programs with like AOL's Greenhouse that Mark Welsh talked about. Netscape is also doing interesting things.

In direct IPO, do not pass Go, do not raise venture money, just go directly to an IPO is a possibility for certain companies that are well-established. But it's interesting that only a very small percentage of Internet companies that have gone public had done it without venture capital first.

Okay, on the next three slides I'll quickly lay out a map of where I see some of the best business opportunities that are still wide open on the Internet. This is a map of the western mining district, and you can see the Comstock load over there in Nevada.

This graph is a little busy, but it's something that I got published in the *Red Herring*. It shows the Internet application layers on the Y axis, it's sort of like the [inaudible] stack where at the bottom you've got the infrastructure with T-1 lines and ISDN, and then you move up to routers and firewalls and intellectual property, and e-mail and browsers. And at the top you've got applications and content. And across the X axis you've got time. So this is a busy slide, but it shows the evolution of the Internet markets over time.

The upper levels are currently wide open. We see a lot of very big product opportunities along the top, things like music and video and various businesses, advertisement, entertainment, shopping. There's a lot of things that just haven't occurred in the upper levels.

And there's some very interesting niches in firewalls and intellectual property protection in some of the lower infrastructure areas.

Here's a second way of thinking about where the opportunities still remain for small companies, and basically it's a statement that every problem on the Web is an opportunity for a business. The Web is unorganized, so there's a huge market for search services. So, as I said, we've got an investment in InfoSeek, which is doing unbelievably well.

Security is a problem. A lot of opportunities in security.

Slow response time, there's a huge opportunity for compression and cable modems, which are two really, really hot markets.

Things like outages. Nobody has addressed moderating flow control software for routers. Cisco is starting to do something about it, but the center-connected "meshnetwork" is going to need a higher degree of organization than even the next generation IP can provide.

Boring pages, lack of multimedia — there's a lot of opportunities in audio/video software, VRML publishing and links with telephony. These are all wide open, and we're talking to a lot of interesting companies that are doing things like this.

Finally, we haven't talked about the impact of the Internet on non-Internet business. Here's four of our portfolio companies in four different areas that are extending their base products with Internet software and services. I mean, eventually the Internet is going to impact all business. And so we're looking to finance the business that can look out and see how the Web is going to effect their business and then apply that technology into a particular vertical market, like sales force automation or medical pay or provider networks.

Here's a quick plug for my firm. We are a leading firm that focuses on software and communications. But I think there are a lot of good firms out there, and if you are in the market to raise money, what you should do is go around and talk to some of the better firms in the market and choose a firm based on who you feel the most comfortable with, who you feel understands your business and would make a good business partner. Because it's really a partnership, it's not just a blown-off financial transaction.

Okay, I'm well within my time limit. There's only one thing I left out, which is George Hearst again. I wanted to complete his story.

After George got the Comstock load going with his venture capital he helped run the mine for a while, and then he sold his position out and made a small fortune. He retired for a little bit, but he later on turned his small fortune into a big fortune, when he developed the [Homestake] mine in South Dakota, which is the biggest gold mine in the United States. He went on to become a United States Senator from California, and he raised his son — you may have heard of him — William Randolph Hearst, who became the most powerful newspaperman in his time.

So there you have it. Raise venture capital and live happily ever after.

Timothy Duncan: We have heard some rumors in Boston that there may be some fidgeting activity in the high technology sector in Northern California. Until they start encroaching in the areas of proprietary word processing systems and micro-computers, we're not going to be too worried, though.

Our next speaker is from Northern California. Bill Bunting has been with Montgomery Securities for eight years, and he spent the last in Montgomery's private placement group focusing on technology. Prior to that he spent three years as a technology mergers and acquisitions banker, and two years in corporate finance, as both a generalist and technology banker. Bill has been involved in both the IPO and private placement for PSI Performance Systems International, and is now working on private placement with Concentric. His education includes an MBA from Harvard in 1987 and an Undergraduate degree from Stanford University.

William Bunting: It's a pleasure being here today. [I want to] just to give you a few of our insights about what's happening in the capital markets, both in the private arena — being late-stage institutional investments — and the public arena. But before I get started, I think it's important to sort of give a backdrop of what's happening in the capital markets away from just Internet financing. 1995 has really been an extraordinary year, particularly when compared to '94, which was by all comparisons a pretty flat year. This year the Dow is up 23%, NASDAQ is up about 35%. But what I think is more important for most of the people in this audience is an understanding about the outlook — will the good times continue, in other words. We are actually quite optimistic, despite this sort of healthy skepticism in the markets today about valuations.

When you look at the fundamentals driving the economy you see moderate growth, low inflation, the prospect that Washington is going to do something on the budget side, a stable dollar and lower interest rates today, all of which suggest that the outlook for investing is pretty good, particularly for financial assets. And I think particularly to the folks in this room, growth stocks are something that I think are going to be tremendous opportunity of looking in the future.

I'd like to talk about four things briefly, and one of the benefits — or curses, I guess — of being the fourth speaker in line is that some these topics have been covered by my distinguished panel members; but let me just see if I can move through this pretty efficiently.

First of all, a little bit of a backdrop of the technology markets and where those have been over the last two years. In 1995 we have a discussion about what's happened with the public markets, the financing for Internet-related companies, because it really has sort of burst onto the scene in a significant way this year. [Let's engage in] a brief discussion about what's happening, how investors are valuing company.
